ACKNOWLEDGEMENT

I begin by expressing my immense gratitude to the almighty lord for his blessings.

My continued reverence and acknowledgement to my beloved teacher and guide ***Dr. Harendra Kumar M.L****, Professor of Pathology and Dean, Faculty of Medicine, who handpicked this topic for me and graced study officially with his constant support and expert advice, his encouragement, wise constructive judgement the painstaking effort to weed out errors and his affection during course of study leaves me permanently indebted to him. I dedicate the good part of the work to him*

I take this opportunity to express my humble and sincere gratitude and indebtedness to my teacher ***Dr. Kalyani R****, Professor and Head of the department for her expert advice, constant support, encouragement and timely help in every aspect.*

I would like to express my gratitude to ***Dr. CSBR Prasad,*** *Professor ,for his constant guidance, support and encouragement.*

I express my sincere and humble gratitude to ***Dr. T.N. Suresh****, Professor, for his support, constructive advice and constant encouragement.*

I express my deep immense gratitude and humble thanks to ***Dr. Subhasish Das****, Professor, for his advice and encouragement throughout the study.*

I would like to convey my sincere thanks to ***Dr. Manjula K*** *and* ***Dr. Hemalatha A,*** *Additional professors, for their constant support throughout the course.*

I wish to express my sense of gratitude to ***Dr. Swaroop Raj B V****, Associate Professor, for his kind help and expert advice in preparing this dissertation*

I express my sincere thanks to ***Dr. Shilpa M D, Dr. Supreetha M S, Dr. Yashaswini R, Dr. Geetha S****, Assistant Professors, for their constant guidance and encouragement in preparing this dissertation.*

My parents, ***Mr. Narayan Reddy, Mrs. Vasantha*** *and my brother* ***Mr. Minith Reddy*** *who have and will always be my biggest source of strength and inspiration, for their unconditional love and support in every aspect of my life, I am forever indebted.*

I express my sincere thanks to my batchmates and friends, ***Dr.Pradeep Mitra, Dr.Manan shah and Dr.Hajra Mehdi*** *for their support and love in every aspect of my life.*

My immense gratitude and special thanks to my juniors and friends, ***Dr. Varsha and Dr Preeti*** *their support and love.*

I enjoyed working with my seniors – ***Dr.Karthik, Dr.Nishit, Dr.Ankita****,* ***Dr.Shubhra, Dr. Argha, Dr. Swathi, Dr. Sulagna and Dr. Rajini*** *and my juniors –* ***Dr. Ankit****,* ***Dr.Gaurav, Dr. Priyanka*** *and* ***Dr. Sonia.*** *I thank them for their kind co-operation.*

I am thankful to ***Dr. Mahesh****, for his guidance in statistics.*

I am thankful to technical staffs and all non-teaching staffs for their invaluable help without whom this study would not have been possible.

Thank you everyone.

ABSTRACT

BACKGROUND:

Tumors of the colon and rectum are one of the most common malignancies worldwide. However, its incidence was less in India compared to the developed countries. In the recent years, due to westernization, sedentary lifestyle and increased consumption of animal fats with less dietary fibre intake have increased the incidence in India in the past few decades. Family history and Microsatellite instability also predisposes the patient to Colo-rectal carcinoma. Many prognostic factors have been studied in Colo-rectal cancers and have been proved. However newer factors like macrophage infiltration in the tumor microenvironment have been studied. Many theories have been put forth to study these macrophages and their sub population M1 and M2. M1 macrophages are considered to be tumoricidal whereas M2 macrophages are considered to promote tumor growth by releasing growth factors and promoting angiogenesis. Hence, the study of these macrophage subpopulation M1 and M2 can help in assessing the prognosis in patients with Colo-rectal cancers.

AIMS & OBJECTIVES:

1. To determine the expression of CD68 and CD163 in Colorectal Cancer

2. To Correlate the expression of CD68 and CD163 with the histological grade and stage of the tumor

MATERIALS AND METHODS:

All Colorectal carcinoma specimens received in the Department of Pathology from R.L.Jalappa Hospital and Research Center attached to Sri Devaraj Urs Medical College, Tamaka, and Kolar from December 2016 to September 2018 and also the paraffin blocks taken from all cases of Colorectal cancer retrieved from Archives of Department of Pathology from the year January 2008 to November 2016 were included in the study.

Data regarding the clinical details (Age, Sex, Histological grading) were collected. Hand E slides were reviewed for Histopathological types, grade and staging of the tumor. Immunohistochemistry for CD68 and CD163 (Biocare mouse antibody) was performed on all cases of Colorectal Carcinoma using appropriate positive and negative controls by peroxidase and anti peroxidase method.

RESULTS:

A total of 62 cases were studied of which 39 were males and 23 were females. The most common site of tumor was Rectum followed by ascending colon. Majority of the tumors were less than 5 cms.The most common grade was moderately differentiated adenocarcinoma. Maximum number of cases were in Stage III, 23 cases(37.1%) Perineural invasion was seen in 2 cases and lymphovascular invasion was seen in 3 cases. Maximum number of cases (64.5%) were in lymphnode ratio less than <0.111.

Expression of CD 68 was significantly correlating with site of the tumor, Size of the tumor, Grade, and lymphnode ratio. Expression of CD 163 was correlating with T stage, N stage, TNM stage, and Lymphnode ratio.

CONCLUSION:

CD 68 expression was associated with better prognostic factors such as smaller size of tumor, lesser grade and lesser lymphnode ratio(LNR) and CD 163 expression was associated with poorer prognostic factors such as higher T stage, Higher N stage, and higher values of lymphnode ratio(LNR). Hence, CD 69 and CD 163 can serve as a reliable prognostic marker in colo-rectal cancers.

Introduction

INTRODUCTION

Tumors of the colon and rectum are the 3 rd most common malignancies in men and second most common malignancy worldwide. [1] They are the 2 nd most common cause of death from cancer.[2] They are included among the most frequently encountered malignancy in the western population and in industrialized countries. The U S SEER database showed that the incidence of colorectal adenocarcinoma was 33.7/100000 and there was an increase of 18% from 1973 to1987.[3] However, in the recent past, there has been a steady increase in the incidence of Colo-rectal cancers in India.

It was estimated that about 875,000 colo-rectal cancer cases were detected in 1996 and constituted to about 8.5% of overall newly detected malignancies.[3]

A variety of environmental and genetic factors play a vital role in the development of these tumors[3]. Tumor microenvironment consisting of leucocytes and fibroblasts are also involved in the progression of colo-rectal cancers.

The concept of macrophages differentiation and activation by classical and alternate pathway in the progression of the disease has been hypothesized and are being studied in the tumors of colon and breast[4].

It has also been studied that the macrophages release cytokines, which favor tumor progression and metastasis[5]

The tumor associated macrophages (TAMs) are broadly classified into two types depending on their mode of activation. The M1 macrophages are activated by classical pathway and M2 macrophages are activated by alternate pathways.

M1 macrophages cause good inflammatory response by releasing pro inflammatory cytokines such as TNF alpha, IL Beta and IL 6 thus fight against the tumor cells and are considered tumoricidal.

The M2 macrophages secrete anti-inflammatory cytokines such as TGF Beta, IL 10 and IL 3 and may help in tumor progression[6].

CD 68 and CD 163 are the proteins expressed by the circulating macrophages, monocyte derived macrophages and tissue macrophages. CD 68 stains cytoplasm of the M1 macrophages that are considered to be tumor suppressive and CD 163 stains the cytoplasm of M2 macrophages that are considered to help in tumor progression.

The patients with Colo-rectal cancer have better prognosis when there is increase density of macrophages at the tumor front which exhibit M1 phenotype, despite the parallel increase of M2 phenotype[7]

On H and E section, it is difficult to differentiate M1 and M2 phenotypes. Hence Immunostaining is used to identify M1 and M2 sub population of macrophages. CD68 is been taken as a marker for M1 macrophage and CD163 is been taken as a marker for M2 macrophage.

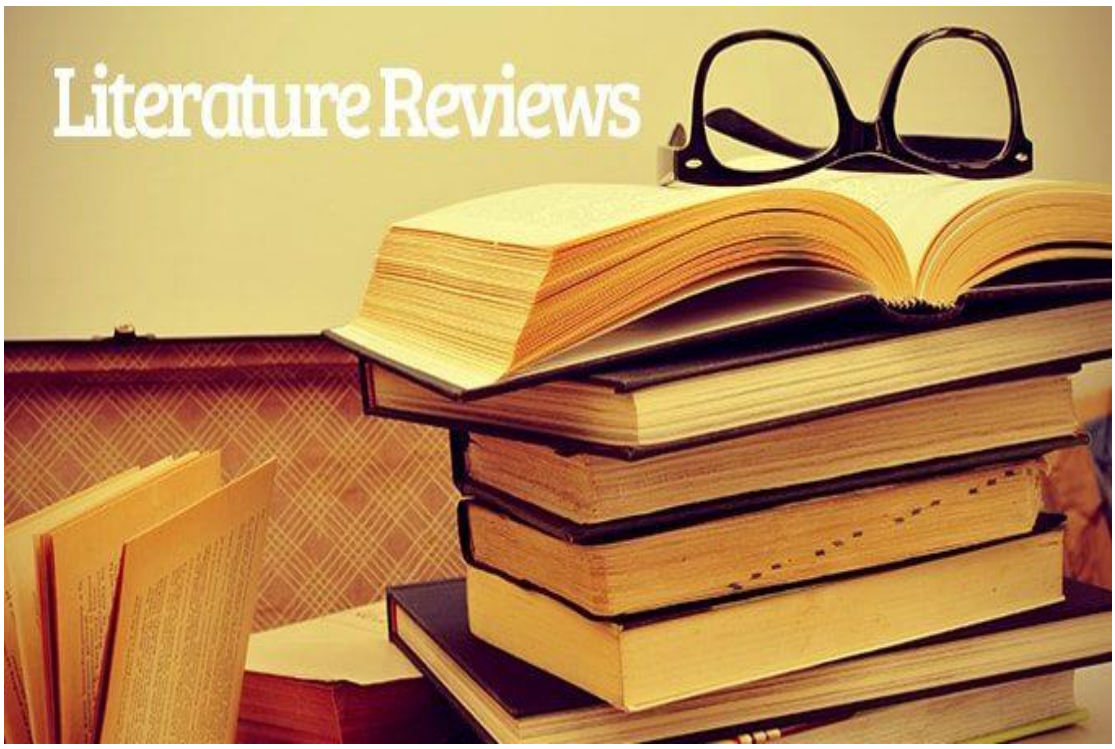
Only few studies determining expression of CD68 and CD163 have been done on Colorectal Cancers and published in Indian Literature so far.

Hence the study is undertaken to determine the expression of CD68 and CD163 in Colorectal Carcinomas.

Aims & Objectives

OBJECTIVES OF THE STUDY

1. To determine the expression of CD68 and CD163 in Colorectal Cancer
2. To Correlate the expression of CD68 and CD163 with the histological grade and stage of the tumor



Literature Reviews

REVIEW OF LITERATURE

EMBRYOLOGY

The caecum, appendix, ascending colon and one half to 2/3rd of transverse colon arises from the hindgut. During development, as early as 6 th week of intrauterine life, the midgut elongates and forms a U- shaped loop called as "Midgut loop" and communicates with the omphaloenteric duct by 10th week.

The midgut loop has a cranial and caudal limb and which is suspended by the mesentry in the abdominal cavity. The cranial loop grows rapidly and forms the intestinal loops.

The caecal swelling is formed by the caudal loop , which appears in the ante mesenteric border of midgut loop which further grows slowly in the apex forming appendix.

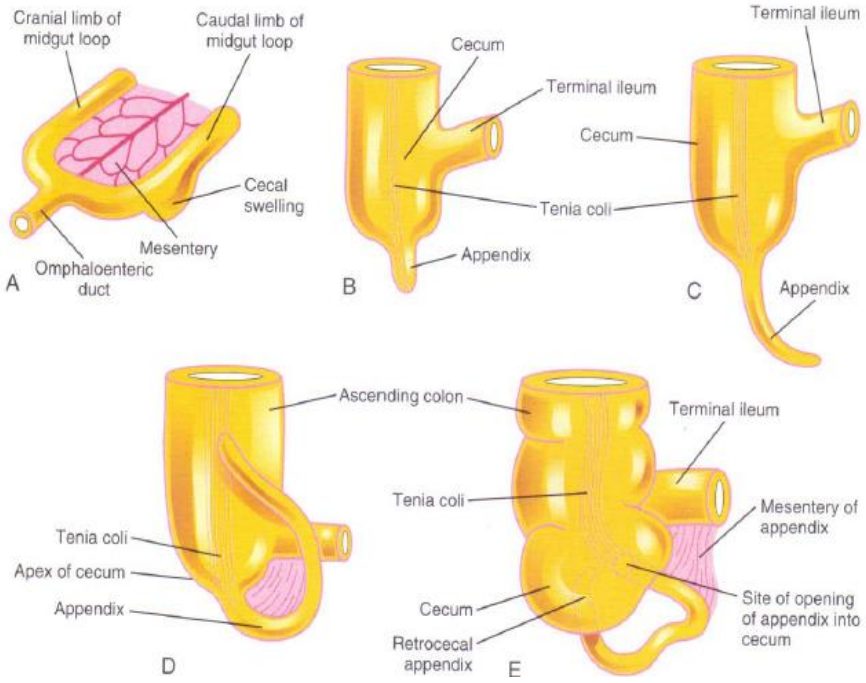


Figure 1 - Showing stages in the developmemt of cecum and appendix. [34]

The Left one third to one half of transverse colon, descending colon, sigmoid colon and part of anal canal is formed by the hindgut. The site of junction of transverse colon developed from the midgut and hindgut is assessed by the blood supply. I.e the part of the transverse colon derived from the midgut is supplied by branch of Superior mesenteric artery whereas the part of transverse colon derived from the hindgut is supplied by branch of Inferior mesenteric artery.

As the mesentery fuses with parietal peritoneum the descending colon becomes retroperitoneal.

The terminal part of hindgut forms the cloaca and plays an important role in the development of Anal canal and rectum. [34]

ANATOMY

The colon and rectum comprises of distal 1-1.5 metres of the gastro intestinal tract and has been divided into Caecum, ascending colon, transverse colon, descending colon, sigmoid colon and rectum. The rectum is about 8-15 cms and ends with Anal canal but has no peritoneal covering.

The main function of colon or large intestine is the absorption of water and salts and push the solid faeces into the rectum during defecation. [32]

GROSS APPEARANCE AND HISTOLOGY

The identification of large intestine on the external surface is done by examination of caecum and appendix. The other identification points in favour of large intestine are

1. Taeniae coli are the three longitudinal muscle bands of smooth muscles over the surface
2. The contractions in smooth muscles of taeniae coli causes bulges and are known as Haustrations.
3. Accumulations of adipose tissue on the visceral surface are called Epiploic appendages [72].

The large bowel is lined by 4 layers namely

1. Mucosa- The Mucosa is subdivided into Epithelium, Lamina propria and muscularis mucosae. The histology remains the same in the entire length of colon from caecum to rectum. Just above the valves of anal canal, mucosa folds itself longitudinally and are known as “Coloumns of Morgagani”.

It consists of two different types of cells- Goblet cells and Absorptive cells. These cells are arranged in tightly packed crypts which extend below and sits on muscularis mucosae. [32]

2. Sub mucosa- Consists of loose connective tissue, blood vessels and Meissners plexus
3. Muscularis Externa- There are two muscle layers in muscularis externa. 1. Inner circular muscle layer. 2. Outer muscle layer forms three bands that are longitudinal and are known as Taeniae coli. The outer longitudinal layer is thin and seen interspersed between taeniae coli. [33]
4. Serosa- It is the outermost layer and is the site of mesenteric attachment to the colon.[33]

The lymphatics of colon drain to Paracolic group, Mediate nodal groups, Central Lymph nodes and Para aortic group of Lymph nodes[2]

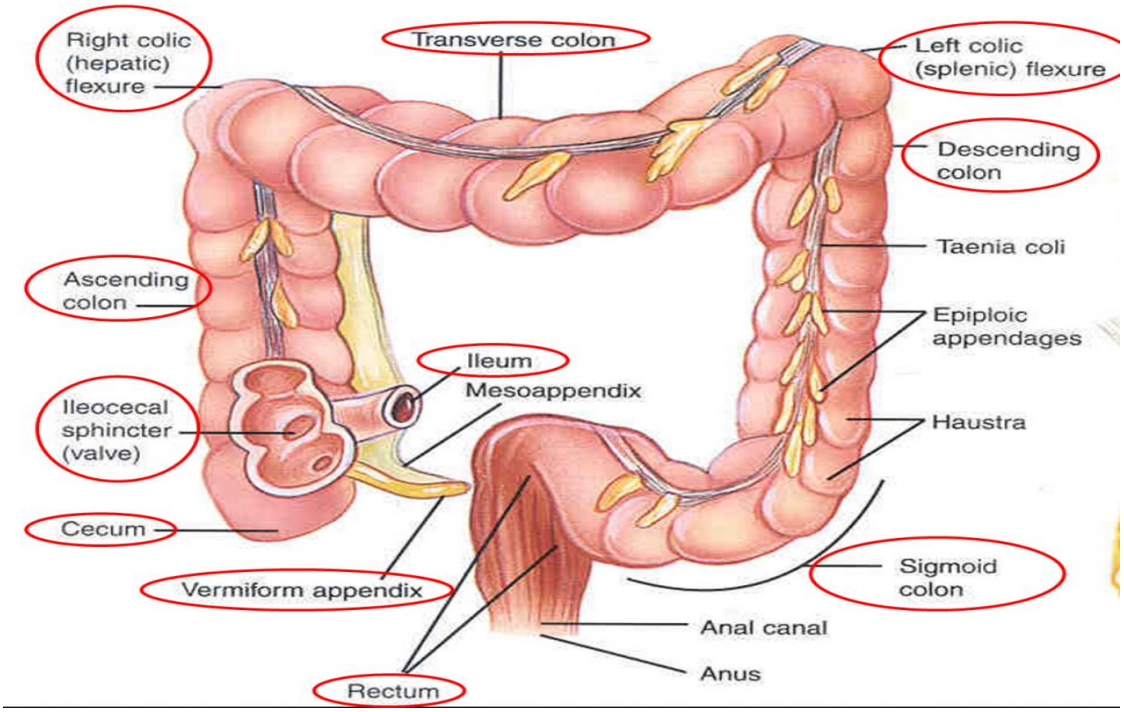

Figure 2 - Anatomy of Colon and Rectum [22]

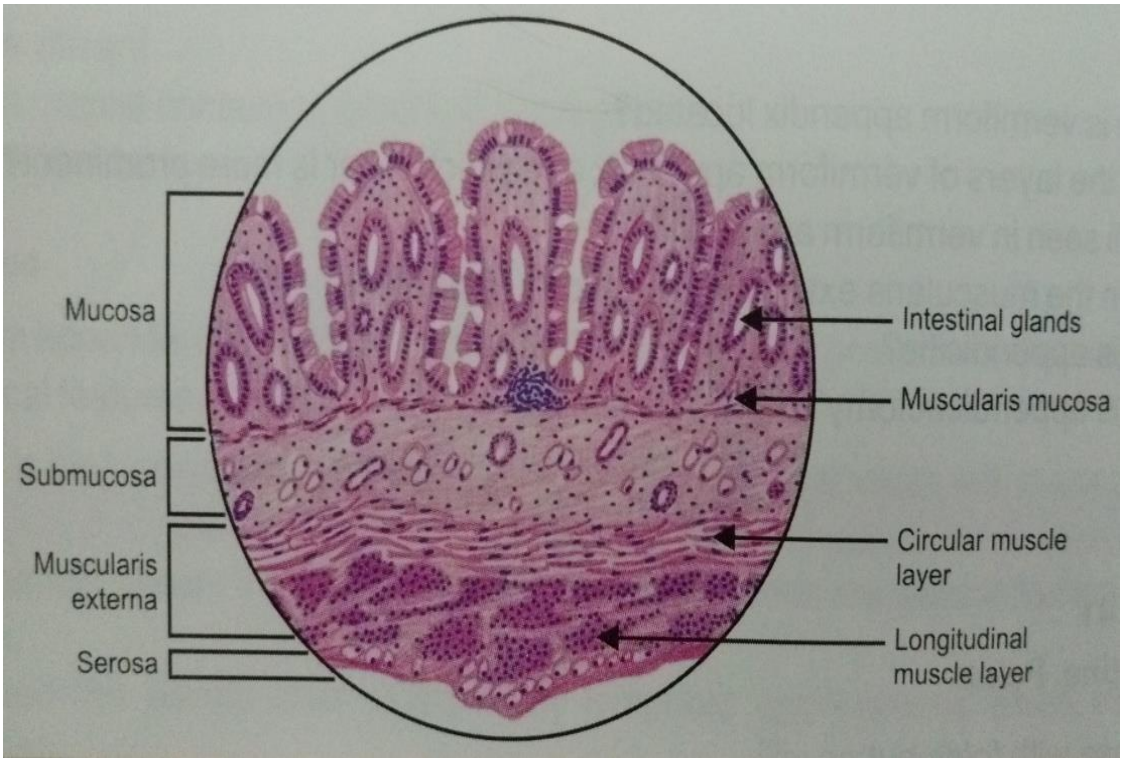

Figure 3 - Histology of Large intestine [23]

INCIDENCE AND EPIDEMIOLOGY:

Colo-rectal cancers are an important cause of morbidity and mortality worldwide and accounts for 9% of all malignancies. There is no sex predeliction but slightly more common in males.

Australia, New Zealand, Canada, the United States, and parts of Europe carry the highest number of cases whereas countries with the lowest risk include China, India, and parts of Africa and South America. It affects about 40/ 100000 population in United States, New Zealand and Australia. [9]

In the year 2016, 134,490 cases of Colo-rectal carcinomas were newly detected in USA and 49,190 cases succumbed to the disease. It is the third most common malignancy in men next to Prostatic and lung cancer in men and in women, it is next to lung cancer and carcinomas of the breast, and cause a heavy burden on health status in United states and worldwide. [25]

Thailand and Japan are burdened with increasing incidence of Colo-rectal malignancies and there has been a steady increase in the past 30 years. Saudi Arabia has been showing the doubling incidence of Colo-rectal carcinoma since 1994 [25].

In United States, It is the second leading cause of death due to cancers. Though the survival in these patients have been influenced by improved diagnostic modalities, its incidence remains unchanged[9]

RISK FACTORS [3,8,9,10,11]

The risk factors for the development of Colo- rectal cancer can be divided into modifiable and non-modifiable risk factors.

NON MODIFIABLE RISK FACTORS

1. Age- More common above the age of 40 years and over 90% of tumors of over 50 years.
2. Adenomatous polyps- A patient with history of adenomas of colon is at increasing risk of developing colo rectal cancer. Over 90% of sporadic tumors arise from these adenomas.
3. Inflammatory bowel disease- A patient with Inflammatory bowel disease is 4-20 times more prone for developing malignancy
4. Family history- A patient with positive family history for colo-rectal cancer or Adenomatous polyps have 20 fold increased risk of developing malignancy
5. Inherited genetic risk- Patients with Familial adenomatous polyposis and Heriditary non polyposis Colo-rectal cancer are at 70-80% higher risk of developing Colo-rectal cancer
6. Ubiquitous somatic mutations- Also known as Microsatellite instability is caused by large number of mutations in the form of insertions or deletions in tumor cells.

MODIFIABLE RISK FACTORS

1. Environmental risk factors- Numerous environmental factors such as lifestyle, urban living, social and cultural practices enhances the risk of developing Colo-rectal cancers.
2. Nutritional practices- Increased animal fat, high meat consumption and reduced dietary fibre intake
3. Physical activity and obesity- Sedentary lifestyle, reduced physical activity and obesity are proved to be a risk factor for colo-rectal cancer
4. Cigarette Smoking- Smoking is an important risk factor for adenomatous polyps and 9 % of colo-rectal cancers are attributed to tobacco smoking.
5. Alcohol Consumption- Heavy alcohol abuse is associated with enhanced risk of colo-rectal cancer.

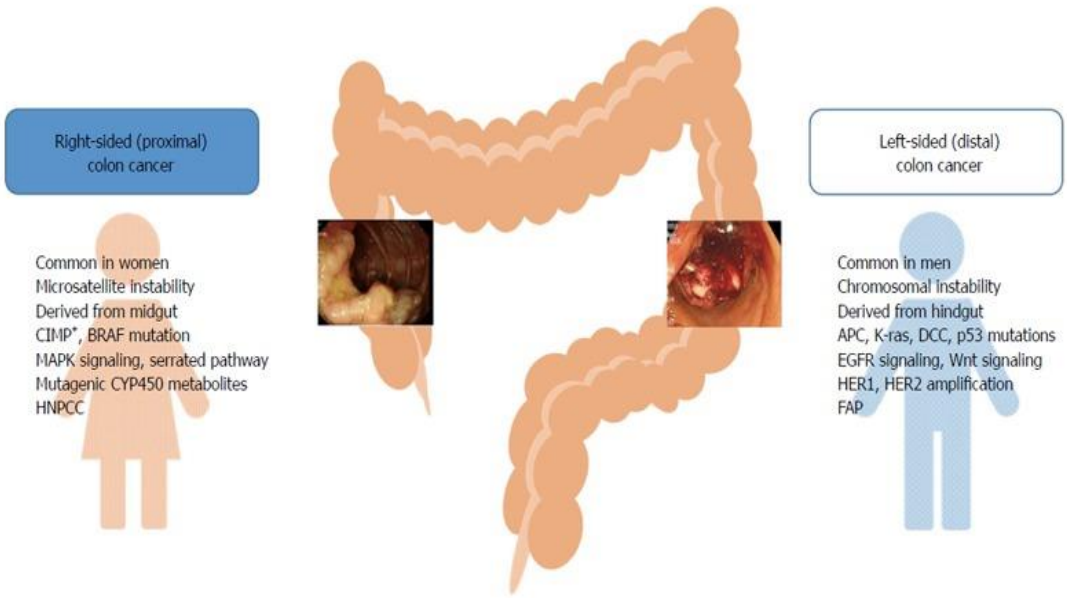

Figure 4- Right and left colon tumors- Clinical and molecular characters[43]

PROTECTIVE FACTORS:

Numerous factors have been proved to be protective for Colo-rectal carcinomas.

1. Consumption of Fish and Fish oils is proved to be a protective factor against colo-rectal carcinoma even in high meat consuming areas. [26]
2. Other factors include the consumption of dietary rich fibres which is considered protective not only for colo-rectal carcinomas but also for other non-infectious bowel disorders. Many of the developed western countries have a low consumption of dietary fibres and may be attributed as cause for the increased incidence. It has been studied that decreased consumption of dietary fibre will induce and increase the carcinogenic changes in intestinal flora leading to increased incidence. [27]

3. High intake of Vitamin D rich food and Calcium supplements have shown to be protective and decrease the incidence of colorectal carcinoma. It has been studied that calcium reduces the proliferation of epithelial lining cells in the colonic mucosa by neutralisation of bile acids, hence reducing the incidence of colon cancer [28]
4. Regular physical exercise has been shown to not only minimize the risk of colonic tumors but also further reduces the morbidity and mortality in detected cases. Exercise has shown to reduce the incidence of colon cancer over 25%[29].
5. Regular use of Aspirin reduces the risk of colon cancer. Studies have shown that the incidence of colo-rectal carcinomas have significantly reduced in patients regularly consuming Aspirin at least twice a week.[30] The hypothesis is that Aspirin inhibits Cycloxigenase- 2 (COX-2) which is the one of the driving parameter in inflammation and progression of colonic tumors. [31]

SCREENING FOR COLO-RECTAL CANCERS:

The process of screening involves the detection of pre-malignant lesions or diagnosis at early stage so as to minimise mortality and morbidity , even earlier to the manifestation of the disease. The advantages of these screening includes-

- Earlier detection
- Lesser economic burden
- Easier to manage
- Less morbidity and mortality [25]

The Centre for Disease Control and Prevention (CDC) and the U.S. Preventive Services Task in USA recommendations are that entire population be screened for Colo-rectal cancers by Sigmoidoscopy, Colonoscopy and Faecal occult blood testing. They recommend regular screening starting from the age of 50 years in normal individuals and even earlier in patients with Inflammatory bowel disease or family history of Familial adenomatous polyposis(FAP) or lynch syndrome [31]

Tumor microenvironment consists of different types of numerous immune cells. Tumor associated macrophages constitute a good number in microenvironment and has a major role to play in progression of tumors. The controversiality of tumor associated macrophages (TAM) in colo-rectal carcinoma has led to numerous studies in the recent years. The TAMs act by changing the tumour cell metabolism, promoting the angiogenesis, remodelling of extra cellular matrix and by altering the other factors in tumor microenvironment. In colo-rectal cancers, TAM s help in the progression of colonic cancers and thus, may further have therapeutic implications [6]

The infiltration of TAMs into the tumor stroma and interaction of these cells with the surrounding microenvironment decides the course of tumor progression. TAM s analyzed using CD163 marker and the results were compared with clinic pathological data. The level of CD 163 expression was more in cases with tumors of high grade and was associated with poorer outcome. It was concluded that TAM infiltrating the tumor stroma is an independent prognostic factor in Colo-rectal carcinomas. [12]

M1 macrophages have microbicidal and tumoricidal activity due to presence of antigen presenting molecules, which is co-stimulatory receptor for lymphocytes and many pro inflammatory cytokines on their surface[13,14].

M2 macrophages are pro- tumorigenic since they produce factors stimulating tumor growth (Eg. Epidermal growth factor, fibroblast growth factor and Transforming growth factor Beta- 1), angiogenesis (Eg. Vascular endothelial growth factor) and tissue Remodelling (Eg. Fibroblast growth factor, fibrin, and matrix metallopeptidases) and also produce immune suppressive cytokines (Eg. IL10 and Transforming growth factor beta).[13,14]

Stroma of the colo-rectal cancers contain a large number of tumor associated macrophages. There is continuous polarisation of anti-tumoral M1 macrophages to M2 macrophages. The inhibition of the EGFR signalling pathway in colon cancer cells alters cytokine secretion and prevents M1 to M2 polarisation thus inhibiting the cancer growth. This can prove to be a great novel therapeutic modality in treatment of colorectal cancers in the coming years. [15]

A study used anti CD-68 antibody for tumor associated macrophages, suggested that TAMs play a significant role in increasing the micro-vessel density and endothelial area and has been postulated that tumor associated macrophages(TAM) have an effect in promoting local tumor growth, invasion and metastasis. Hence agents targeting TAMs can be of help in controlling the tumor growth in these cancers. [16]

CLINICAL FEATURES:

The clinical presentation usually occurs after the disease has been in an advanced stage and most of the CRC patients present with vague abdominal discomfort, altered bowel habits and bleeding per rectum and anemia.

Tumors of descending colon and sigmoid colon may present with obstructive symptoms and these symptoms are less frequently encountered in right colon. A colonoscopic appearance and biopsy from the suspicious site may yield a definitive diagnosis. [17]

WHO HISTOLOGICAL CLASSIFICATION OF TUMOURS OF THE COLON AND RECTUM [3]

Epithelial tumours

Adenoma

Tubular

Villous

Tubulovillous

Serrated

Intraepithelial neoplasia (dysplasia) associated with chronic inflammatory diseases

Low-grade glandular intraepithelial neoplasia

Secondary tumours

Polyps

Hyperplastic (metaplastic)

Peutz-Jeghers

Juvenile

TUBULAR ADENOMAS

Commonly known as Adenomatous polyps and are usually uniformly distributed in all parts of large intestine and less commonly in the rectum. They are usually asymptomatic and may sometimes cause altered bowel habits. Usually less than 1 cms in size and may be sessile or pedunculated. There is Glandular hyperplasia with cellular crowding and may have atypical nuclear features. Immuno expression shows increased positivity for Carcino embryonic antigen (CEA) especially in the atypical areas. [17]

VILLOUS ADENOMA

They are usually solitary and seen in elderly patients. Though Rectum and recto sigmoid areas are the most common site, they can be easily missed even by digital examination as the lesions are very soft. They have a wide base and finger like villi radiate from base. Light microscopy may show crown like pattern with long papillary structures. Treatment depends on the size and extent of the lesion. The risk of progression to malignancy is as high as 29%- 70%. [17]

SERRATED ADENOMAS

They are usually sessile, small measuring not more than 5 mms. They are designated as serrated as the appearance resembles the saw toothed architecture on light microscopy. They have infoldings of the glands into the lumen and are characteristic. Increased mitotic activity may also be seen. [17]

ADENOCARCINOMA

The minimum criteria to be designated as carcinoma is that the tumor cells should completely breech the muscularis mucosae into the sub mucosa. They are usually asyptomatic and most common mode of presentation is change in the bowel habits, haematochezia or anemia for evaluation. Colonoscopy may aid in the early diagnosis. The pattern of growth may be exophytic, with intraluminal growth, diffusely infiltrative/ linitis plastic type with endophytic growth or with complete circumferential involvement. [17]

MUCINOUS CARCINOMA - Maliganant cells with extra cellular mucin pools more than 50% are designated. Usually asoociated with micro satellite instability

SIGNET RING CELL CARCINOMA- The cells should have peripherally placed nucleus with mucin inside the cells and the cells should comprise of more than 50 % population of tumor cells

ADENOSQUAMOUS CARCINOMA- The entity should have mixture of both adenocarcinoma component and squamous cell carcinoma. The foci of squamous cell carcinoma should be convincing and more than one component should be present.

MEDULLARY CARCINOMA- It is a rare tumor with pretty good prognosis and characterised by presence of tumor cells in solid pattern having vesicular nucleus, prominent nucleoli and eosinophilic cytoplasm. [3]

TNM CLASSIFICATION OF TUMOURS OF THE COLON AND RECTUM [3]

T – Primary Tumour

TX Primary tumour cannot be assessed

T0 No evidence of primary tumour

Tis Carcinoma in situ: intraepithelial or invasion of lamina propria3

T1 Tumour invades submucosa

T2 Tumour invades muscularis propria

T3 Tumour invades through muscularis propria into subserosa or into non-peritonealized pericolic or perirectal tissues

T4 Tumour directly invades other organs or structures and/or perforates visceral peritoneum

Lymph nodes

N – Regional Lymph Nodes

NX Regional lymph nodes cannot be assessed

N0 No regional lymph node metastasis

N1 Metastasis in 1 to 3 regional lymph nodes

N2 Metastasis in 4 or more regional lymph nodes

Metastasis

M – Distant Metastasis

MX Distant metastasis cannot be assessed

M0 No distant metastasis

M1 Distant metastasis

Table-1: TNM STAGING OF TUMORS OF COLON AND RECTUM

Stage 0	Tis	N0	M0
Stage 1	T1	N0	M0
	T2	N0	M0
Stage 2	T3	N0	M0
	T4	N0	M0
Stage 3	Any T	N1	M0
	Any T	N2	M0
Stage 4	Any T	N1	M1

DUKES CLASSIFICATION [73]

1. Dukes A: Invasion into but not through the bowel wall
2. Dukes B: Invasion through the bowel wall penetrating the muscle layer but not involving lymph nodes
3. Dukes C: Involvement of lymph nodes
4. Dukes D: Widespread metastases

ASTLER-COLLER CLASSIFICATION [74]

1. Stage A: Limited to mucosa

2. Stage B1: Extending into muscularis propria but not penetrating through it; nodes not involved

3. Stage B2: Penetrating through muscularis propria; nodes not involved

4. Stage C1: Extending into muscularis propria but not penetrating through it. Nodes involved

5. Stage C2: Penetrating through muscularis propria. Nodes involved

6. Stage D: Distant metastatic spread

These two staging systems are no longer used and are completely replaced by TNM staging system.

Table -2: Comparison TNM, DUKES and Modified Astler-Coller classification system

CD 68 (CLUSTER OF DIFFERENTIATION 68)

Also known as Macrosialin, CD 68 is a 110 kD transmembrane glycoprotein containing 354 amino acids and an important member of scavenger family. It is encoded by CD 68 gene on chromosome 17. Normally it stains cells of macrophage, lineage including Kuffer cells and osteoclasts.

The binding of CD 68 to selectins and organ specific lectins is mediated by Glycosylated extra cellular domain on its surface. Its functions include activation and recruitment of macrophages in a specific site, engulfment of dead cells (Phagocytosis) and foreign bodies.

The lysosomes and late endosomes of the macrophages express CD 68 antigen in the granules thus giving a cytoplasmic staining.

CD 68 positive TAM s in the tumour microenvironment show high serum and stromal levels of VEGF .In this way, by altering the tumor microenvironment, it not only facilitates angiogenesis in the tumour but also reduces the response the tumor to radiotherapy. [18] There is an established fact that increased macrophage index and high vascular grade is negatively associated with reduced relapse free survival and reduced overall survival and is a poor prognostic factor. [19]

Contrary to this, many studies have also shown that M1 macrophages are associated with lesser grade of tumor and better survival in colo-rectal cancers by release of pro-inflammatory cytokines and other inflammatory mediators.

CD 163 (Cluster of differentiation 163)

It is a member of scavenger receptor family and is in a resident tissue macrophage. It acts a receptor for haemoglobin haptoglobin complex and has a pivotal role to perform in body's immune mechanism in response to intravascular and extravascular hemolysis and many bacterial infections. [20]

It has a molecular size of 130 k Da and has 1048 amino acid residues in extracellular domains. A dissolved form of CD 163 is seen in cerebrospinal fluid and is called sCD 163 represents receptor shedding and structural and functional modulation of CD163.

sCD 163 is upregulated in disease likes Diabetes, Gauchers disease, Rheumatoid arthritis and Hodgkin's lymphoma.

Numerous studies have shown than higher expression of CD 163 molecule in Colo-rectal cancers are associated with higher chances of lymph node metastasis, higher grade, increased tumour size and higher chances to tumor recurrence. [21]

PROGNOSTIC FACTORS:

1. Sex- Males have a poorer prognosis compared to females.
2. Age- Extremes of age (Young and elderly) are associated with poorer prognosis.
3. CEA levels- Levels >5 ng/ dl are associated with poor prognosis.
4. Locations- There are studies to prove that tumors involving left side of colon are associated with higher relapse free survival.
5. Inflammation- Tumors having dense inflammation in the tissue tumor interphase are considered as host's response against the tumor cells and are associated with better prognosis.
6. Tumor budding- Presence of isolated tumor cells or cluster of > 5 cells at the invasive front are associate with poor prognosis.
7. Vascular invasion- Invasion of the blood vessel by the tumor cells is a well known prognostic factor and associated with poorer prognosis.
8. Perforation- Large tumors causing perforation are at higher stage and associated with bad prognosis.
9. Lymph node involvement- Involvement of lymph node by the tumor cells increases the stage and associated with bad prognosis.
10. Stage- Higher stage is associated with poor prognosis
11. Grade- Well differentiated tumors (Grade I) are associated with better survival than grade III tumors [17]

MATERIALS &
METHODS

METHODOLOGY

STUDY DESIGN – Observational study.

SOURCE OF DATA : All Colorectal carcinoma specimens received in the Department of Pathology from R.L.Jalappa Hospital and Research Center attached to Sri Devaraj Urs Medical College, Tamaka, and Kolar from December 2016 to September 2018 and also the paraffin blocks taken from all cases of Colorectal cancer retrieved from Archives of Department of Pathology from the year January 2008 to November 2016 were included in the study.

DURATION OF STUDY – Two years

METHOD OF COLLECTION:

All resected Colorectal Carcinoma Specimens confirmed by histopathological examination were included in the study**.**

Data regarding the clinical details (Age, Sex, Histological grading) were collected. Hand E slides were reviewed for Histopathological types, grade and staging of the tumor.

Immunohistochemical staining for CD68 and CD163 (Biocare mouse antibody) was performed on all cases of Colorectal Carcinoma using appropriate positive and negative controls by peroxidase and anti peroxidase method.

PROTOCOL

1) Section Cutting

Sections are cut at approximately 3-4 µ m, floated on to positive charged slides and incubated at 37degree c for one day and further incubated at 58° c overnight.

2) Deparaffinization and Dexylinisation

Xylene –I - 15 mins

Xylene –I I - 15 mins

Ab alcohol – I - 1min

Ab alcohol – II - 1min

90%Alcohol – 1min

70%Alcohol -1min

3) Tap water – 10 min washing

4) Distilled water – 5 min rinsing

5) Antigen Retrieval

Microwave at power 10 for 2 cycles of 6 minutes each in TRIS EDTA BUFFER of PH 9.0. Slides cooled to room temperature.

6) Peroxidase block- 25 min

7) TBS buffer- 3 times wash of 5 min each.

8) Power block- 20 min

9) Drain and cover section with TARGET Ab- 45 min

10) TBS buffer- 3 times wash of 5 min each

11) Probe- 30 min

12) TBS buffer- 3 times wash of 5 min each

13) Super sensitive polyp –HRP- 1 hour 15 min

14) TBS buffer - 3 times wash of 5 min each

15) DAB Color development – 30 min

16) TBS buffer - 3 times wash of 5 min each

17) Hematoxylin Counter stain- 1 min

18) Tap water- 5 min

19) Dehydrate with Xylene

20) Mount with DPX

POSITIVE CONTROL- Tonsil tissue containing macrophages were taken as positive control

TUMOR SIZE

The tumor size was divided two groups. I.e tumors with size less than 5 cms (< 5) and more than 5 cms (>5) according to the study done by Ohnishi K et al [68] on Prognostic role of CD 169 positive macrophages in Colo-rectal cancers.

SELECTION OF HOT SPOTS AND GRADING OF IHC

The CD 68 and CD 163 immuno stained smears were examined under low magnification (10X) and was looked for areas with maximum expression of CD 68 and CD 163 by two observers and were called as" Hot spots" . These hotspots were then viewed under higher magnification (40X) and CD 68 and CD 163 positive cells were counted and the mean was taken. Expression of macrophages antigen CD 68 and CD 163 were graded with the proportion of macrophages staining positive in the tumor stroma. Out of hundred cells counted and the grading is a follows[35, 69]

GRADE+1: Less than 10% cells positive

GRADE+2: More than 10% & less than 50% cells positive

GRADE+3: More than 50% cells positive

LYMPH NODE RATIO(LNR)

Lymph node ratio is the ratio of number of Lymph node with metastasis to the number of Lymph nodes harvested. In the study, LNR was divided into 4 groups according to the study done by Ren JQ et al [70].

LNR 1 - ≤ 0.111

LNR 2 - 0.111 0 to ≤0.200

LNR 3 - 0.200 to ≤0.429

LNR 4 - > 0.429

SAMPLE SIZE

Sample size was estimated by using the proportion of CD163 marker positivity in Colo-rectal cancers in study done by Ivan Shabo et al [12] which was 20% by using the formula

$$\text{Sample size} = \frac{Z_{1-\alpha/2}{}^2 p(1-p)}{d^2}$$

Here

$Z_{1-\alpha/2}$ = Is standard normal variate (at 5% type 1 error ($P<0.05$) it is 1.96 and at 1% type 1 error ($P<0.01$) it is 2.58). As in majority of studies P values are considered significant below 0.05 hence 1.96 is used in formula.
p = Expected proportion in population based on previous studies or pilot studies.
d = Absolute error or precision – Has to be decided by researcher.

P = 20 or 0.20

q = 80 or 0.80

d = 10% or 0.10

Using the above values at 95% Confidence level a sample size of 62 subjects with primary colorectal cancers were included in the study.

STATISTICAL ANALYSIS

Data was entered into Microsoft excel data sheet and was analysed using SPSS 22 version software. Categorical data was represented in the form of Frequencies and proportions. **Chi-square test** was used as test of significance for qualitative data.

Continuous data was represented as mean and SD. **ANOVA (Analysis of Variance) or Kruskal Wallis test** was the test of significance to identify the mean difference between more than two groups for quantitative and qualitative data respectively.

Graphical representation of data: MS Excel and MS word was used to obtain various types of graphs such as bar diagram, Pie diagram.

p value (Probability that the result is true) of <0.05 was considered as statistically significant after assuming all the rules of statistical tests.

Statistical software: MS Excel**,** SPSS version 22 **(**IBM SPSS Statistics, Somers NY, USA) was used to analyse data.

INCLUSION CRITERIA: All Colorectal Carcinoma Cases.

EXCLUSION CRITERIA:

1. Metastatic tumor to Colo-rectal region.

2. Recurrent lesion.

3. Patient subjected for chemotherapy and Radiotherapy

RESULTS

RESULTS

Table 3: Age distribution of subjects in the study group

		Frequency	Percent(%)
Age	<60 years	42	67.7
	>60 years	20	32.3
	Total	62	100.0

In the study, 67.7%of cases were in the age group <60 years, 32.3% were in the age group >60 years.

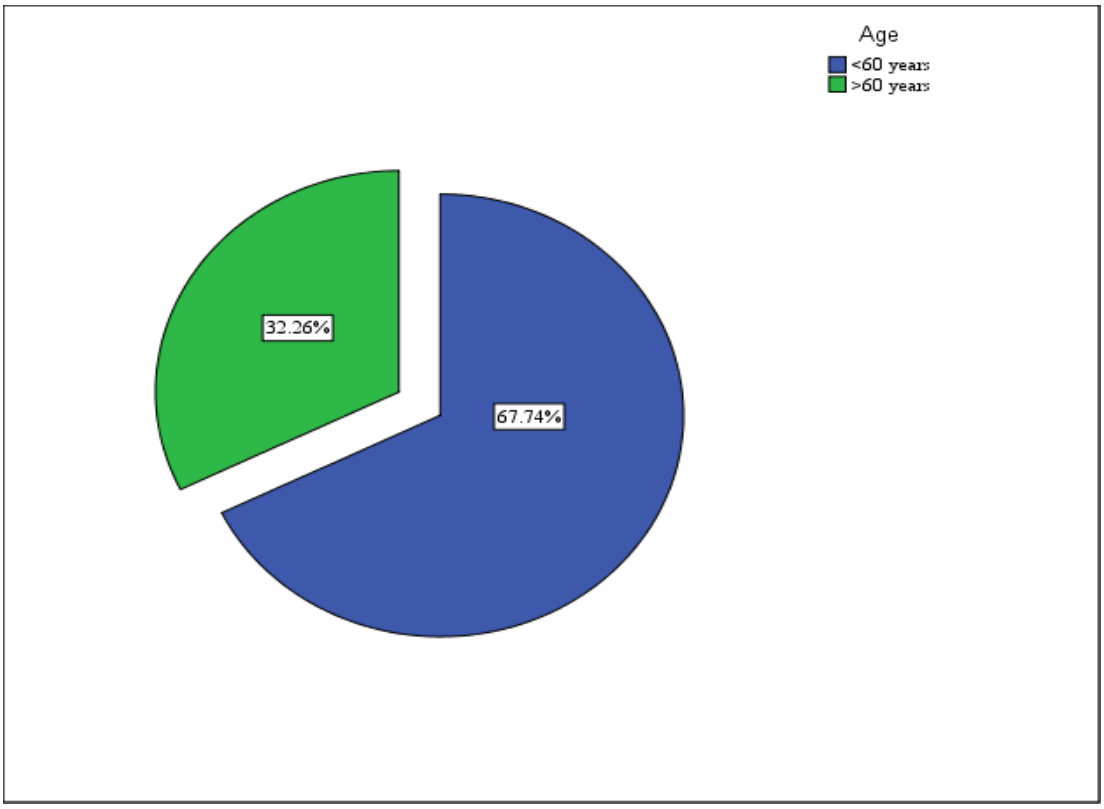

Chart 1: Pie diagram showing Age distribution of subjects in the study

Table 4: Gender distribution of subjects in the study group

		Frequency	Percent(%)
Sex	Male	39	62.9
	Female	23	37.1
	Total	62	100.0

In the study, 62.9% of cases were males and 37.1% were males.

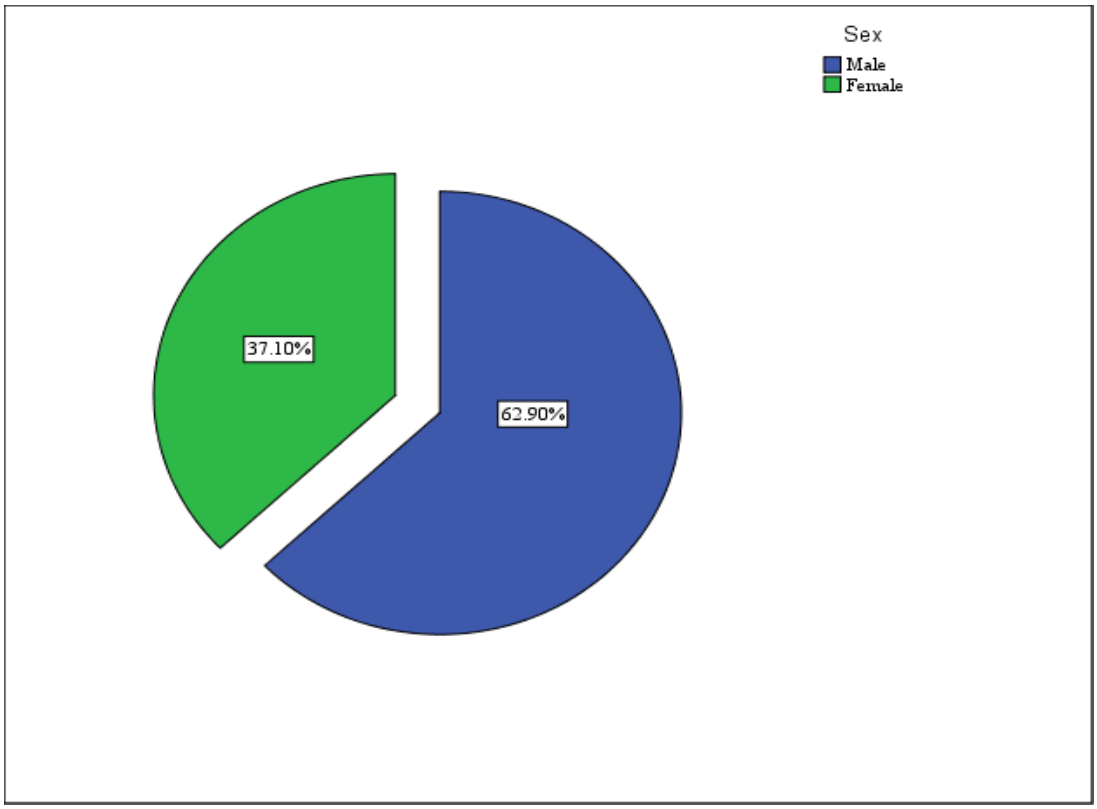

Chart 2: Pie diagram showing Sex distribution of subjects in the study

Table 5: Site of tumor distribution among subjects

		Frequency	Percent(%)
Site	Ascending Colon	13	21.0
	Transverse Colon	6	9.7
	Descending Colon	3	4.8
	Sigmoid Colon	13	21.0
	Rectum	27	43.5
	Total	62	100.0

In the study, the most common site of malignancy was Rectum in 43.5% od cases, followed by ascending colon and sigmoid colon in 21% each , transverse colon in 9.7% and descending colon in 4.8% of cases.

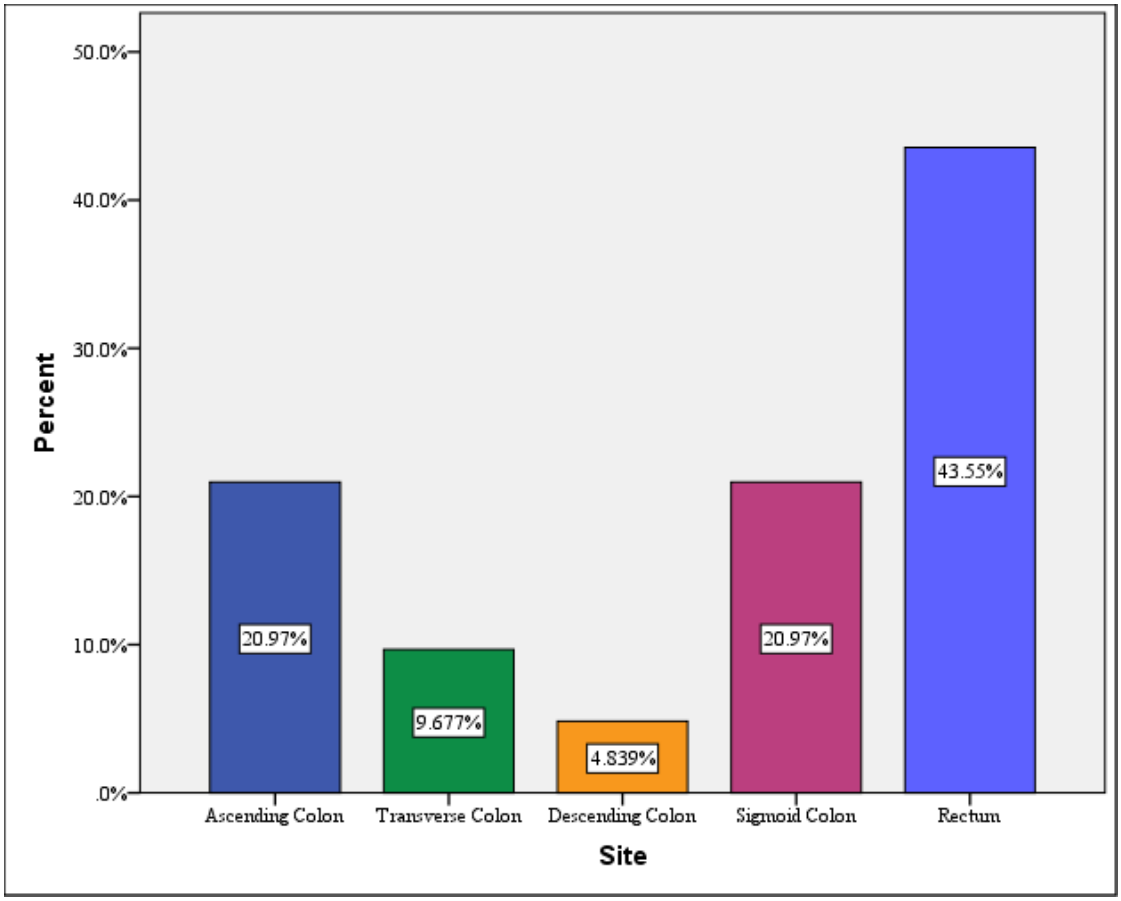

Chart 3 : Bar diagram showing Site of lesion distribution among subjects

Table 6: Type of tumor growth among study subjects

		Frequency	Percent(%)
Growth	Proliferative	8	12.9
	Ulceroproliferative	34	54.8
	Ulcerative/ Infiltrative	20	32.3
	Total	62	100.0

In the study, the most common type of tumor growth was Ulceroproliferative type in 54.8% of subjects followed by Ulcerative/ Infiltrative in 32.3% and proliferative in 12.9% of cases.

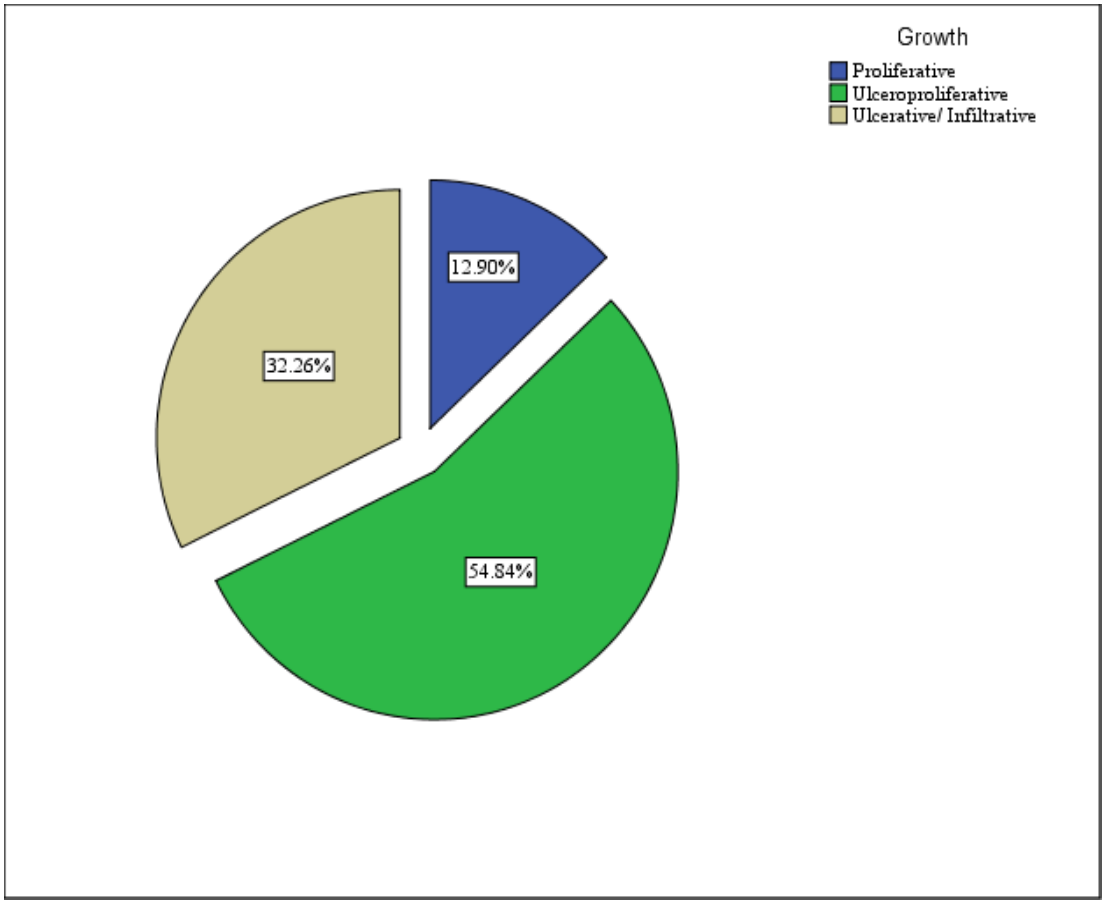

Chart 4 : Pie diagram showing type of Growth distribution among subjects

Table 7: Type of gross specimen distribution among subjects

		Frequency	Percent(%)
Specimen Type	Hemicolectomy	39	62.9
	Abdominoperineal resection(APR)	14	22.6
	Anterior Resection	9	14.5
	Total	62	100.0

In the study, the most common specimen type received was Hemicolectomy in 62.9% of cases followed by APR in 22.6% and Anterior resection in 14.5% of cases.

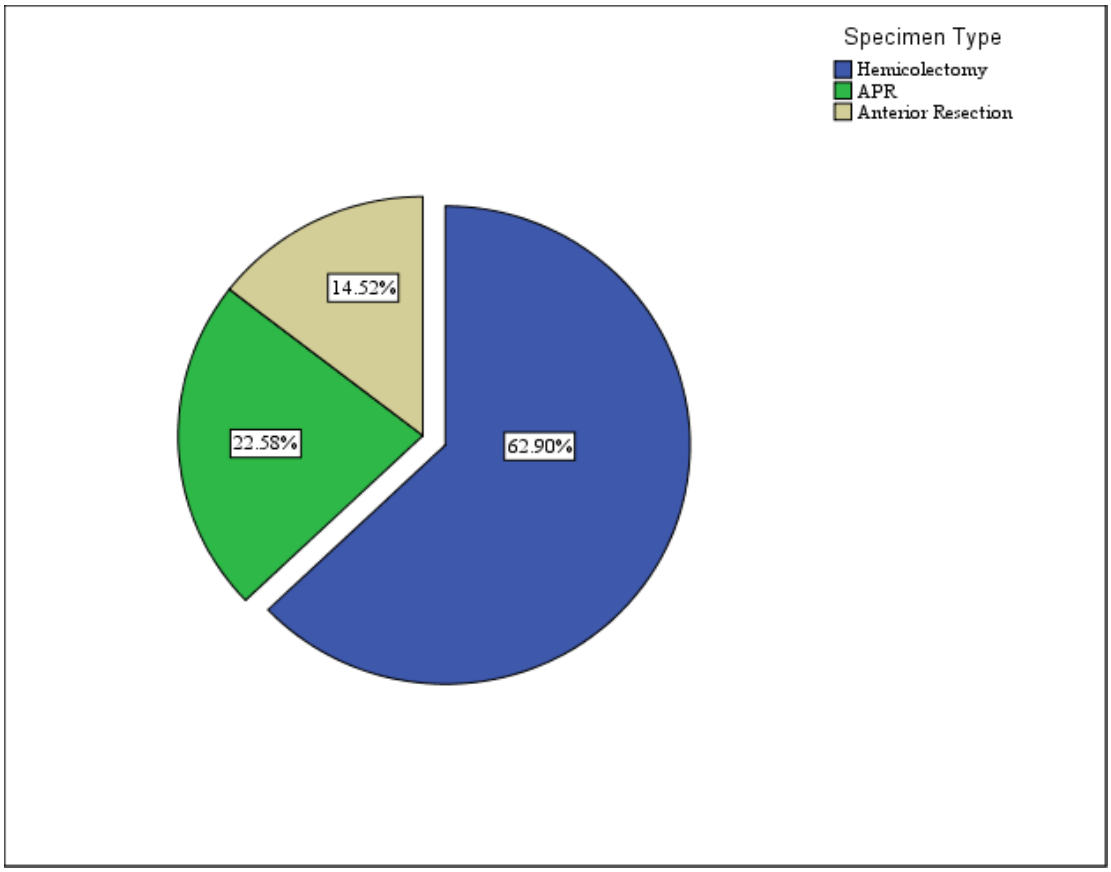

Chart 5: Pie diagram showing Specimen Type distribution among subjects

Table 8: Tumor Size distribution among subjects

		Frequency	Percent(%)
Tumor Size [68]	<50 mms	39	62.9
	>50 mms	23	37.1
	Total	62	100.0

In the study, 62.9% of cases had tumor size <50 mms and 37.1% of cases had tumor size >50 mms.

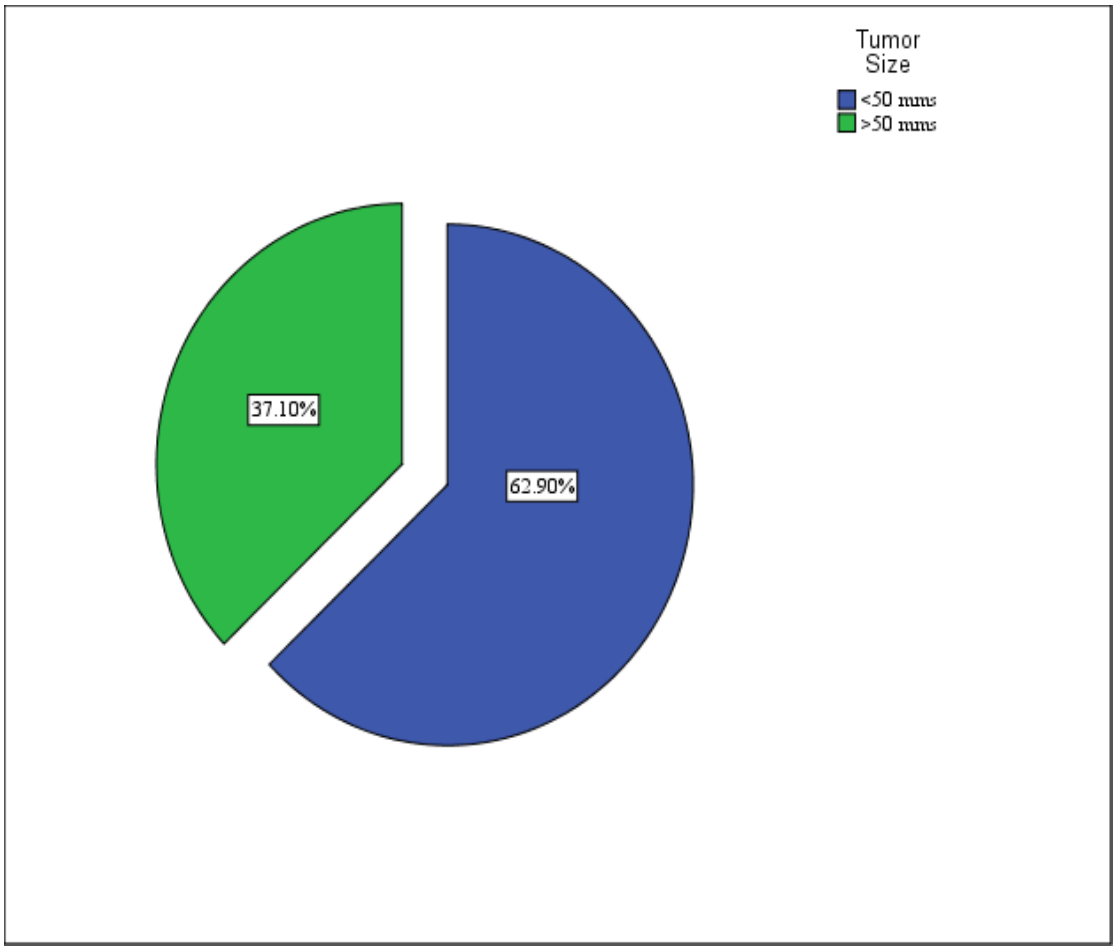

Chart 6: Pie diagram showing Tumor Size distribution among subjects

Table 9: Grading of Malignancy distribution among subjects

		Frequency	Percent(%)
Malignancy Grading	Well Differentiated	20	32.3
	Moderately Differentiated	30	48.4
	Poorly Differentiated	12	19.4
	Total	62	100.0

In the study,32.3% of cases were well differentiated carcinomas, 48.4% were moderately differentiated and 19.4% were poorly differentiated.

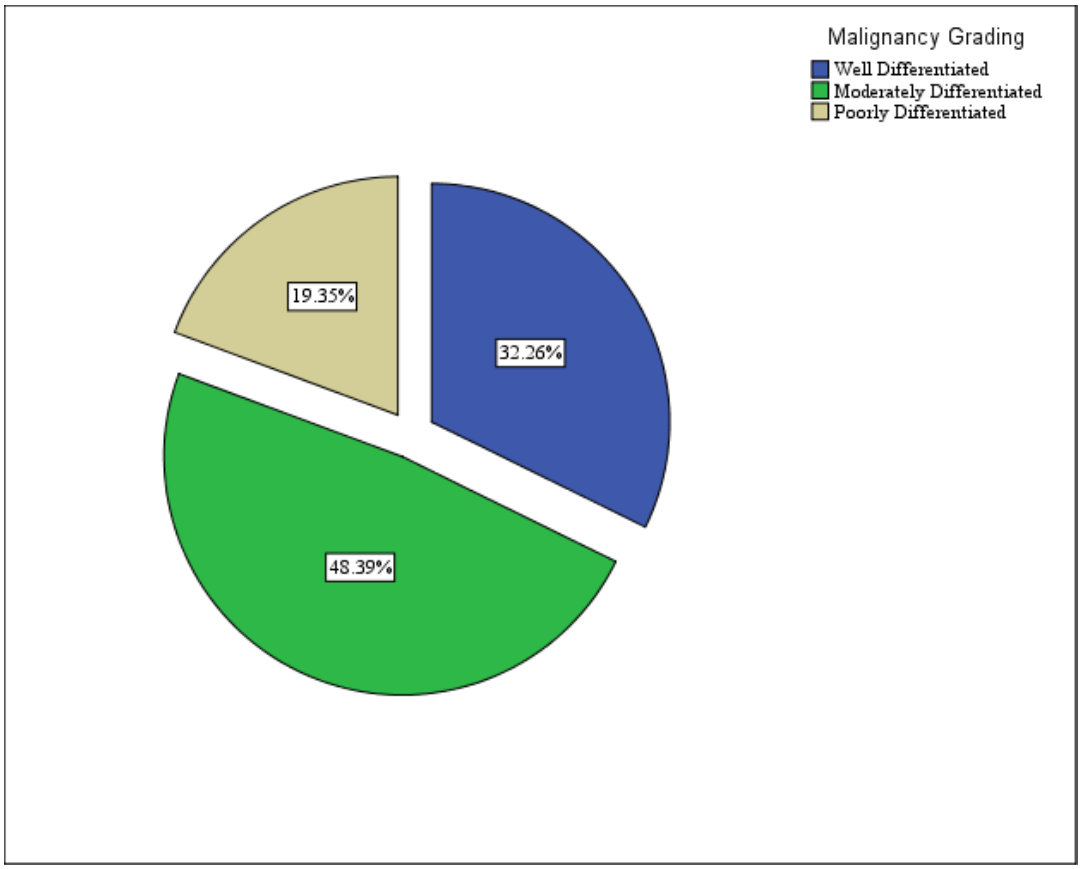

Chart 7 : Pie diagram showing Malignancy grading distribution among subjects

Table 10: T staging distribution among subjects

		Frequency	Percent(%)
T Staging	T1	4	6.5
	T2	16	25.8
	T3	32	51.6
	T4	10	16.1
	Total	62	100.0

In the study, 6.5% of cases were in T1 stage, 25.8% were in T2 stage, 51.6% were in T3 Stage, 16.1% were in T4 Stage.

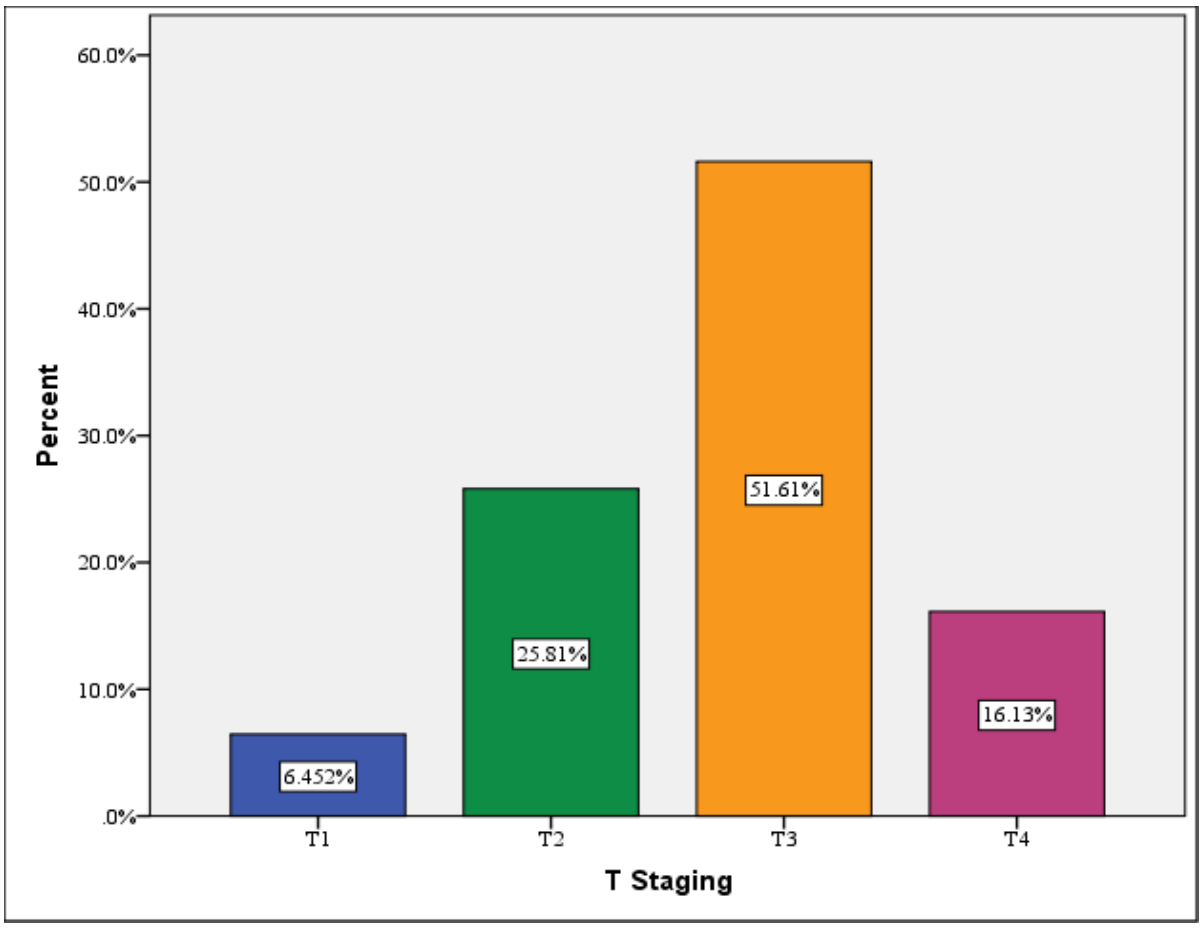

Chart 8 : Bar diagram showing T staging distribution among subjects

Table 11: N staging distribution among subjects

		Frequency	Percent(%)
N Staging	N0	39	62.9
	N1	21	33.9
	N2	2	3.2
	Total	62	100.0

In the stud, 62.9% of cases were in N0 stage, 33.9% were in N1 stage and 3.2% were in N2 stage.

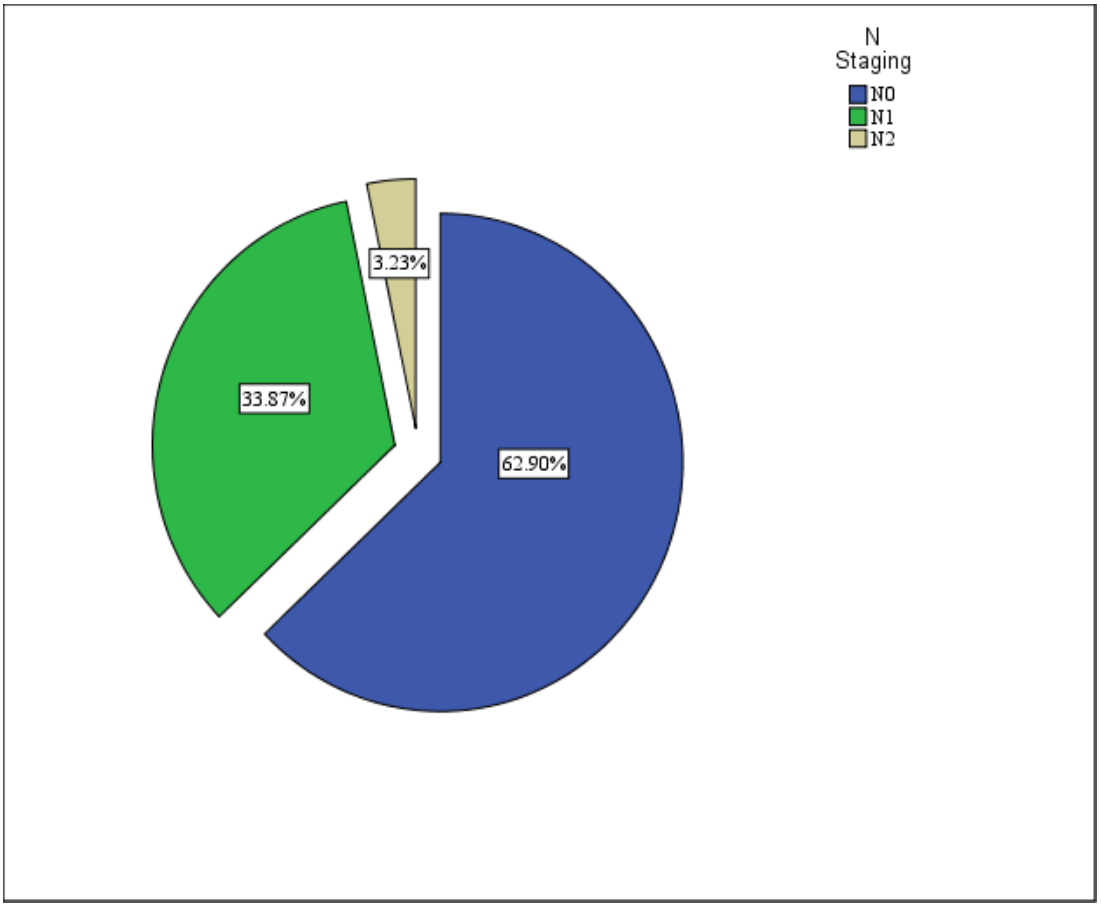

Chart 9: Pie diagram showing N staging distribution among subjects

Table 12 : Stage of Tumor distribution among subjects

		Frequency	Percent(%)
Stage of Tumor	I	17	27.4
	II	22	35.5
	III	23	37.1
	Total	62	100.0

In the study 27.4% were in Stage I, 35.5% were in Stage II and 37.1% were in Stage III.

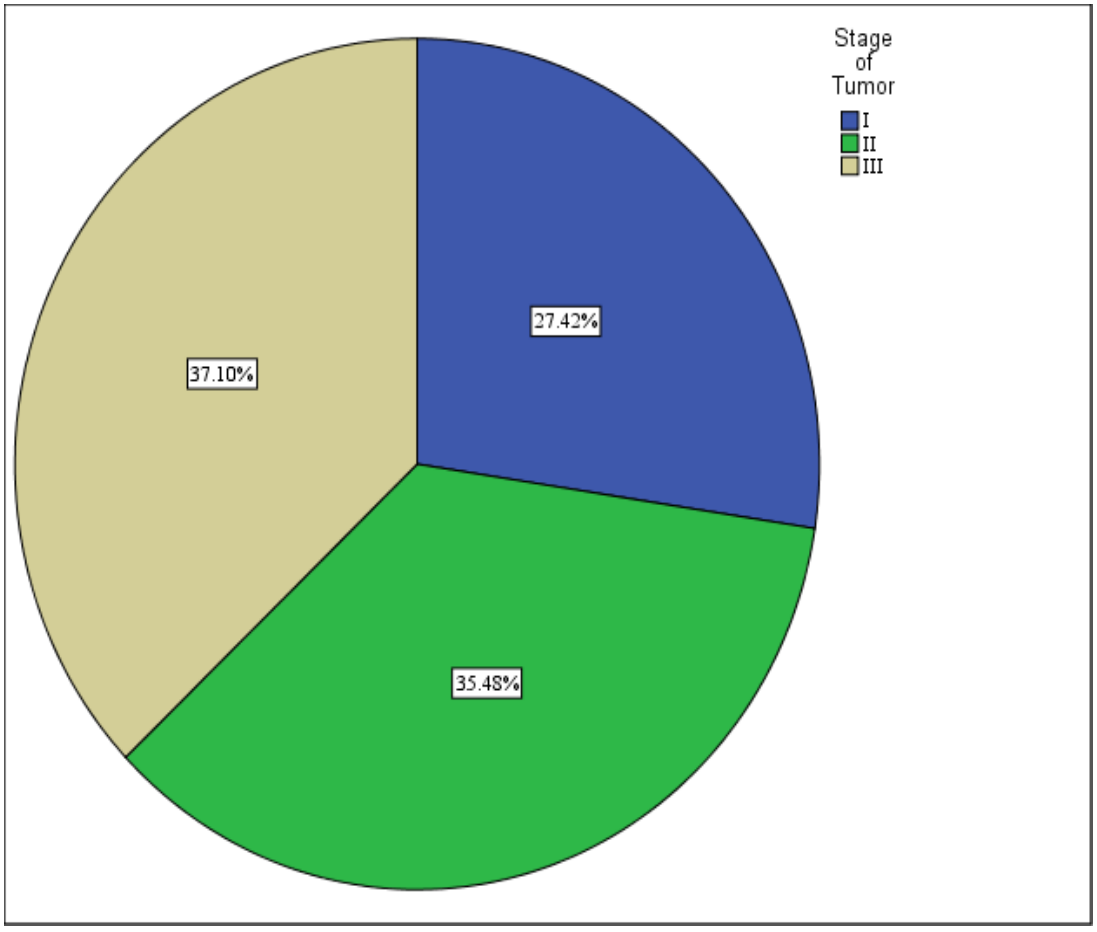

Chart 10 : Pie diagram showing Stage of Tumor distribution among subjects

Table 13: Other parameters in the study subjects

		Frequency	Percent(%)
Perineural Invasion	Absent	60	96.8
	Present	2	3.2
Lymphovascular Invasion	Absent	59	95.2
	Present	3	4.8

In the study 3.2% of cases had Perineural Invasion, 4.8% of cases had Lymphovascular Invasion and 4.8% of cases had Perforation.

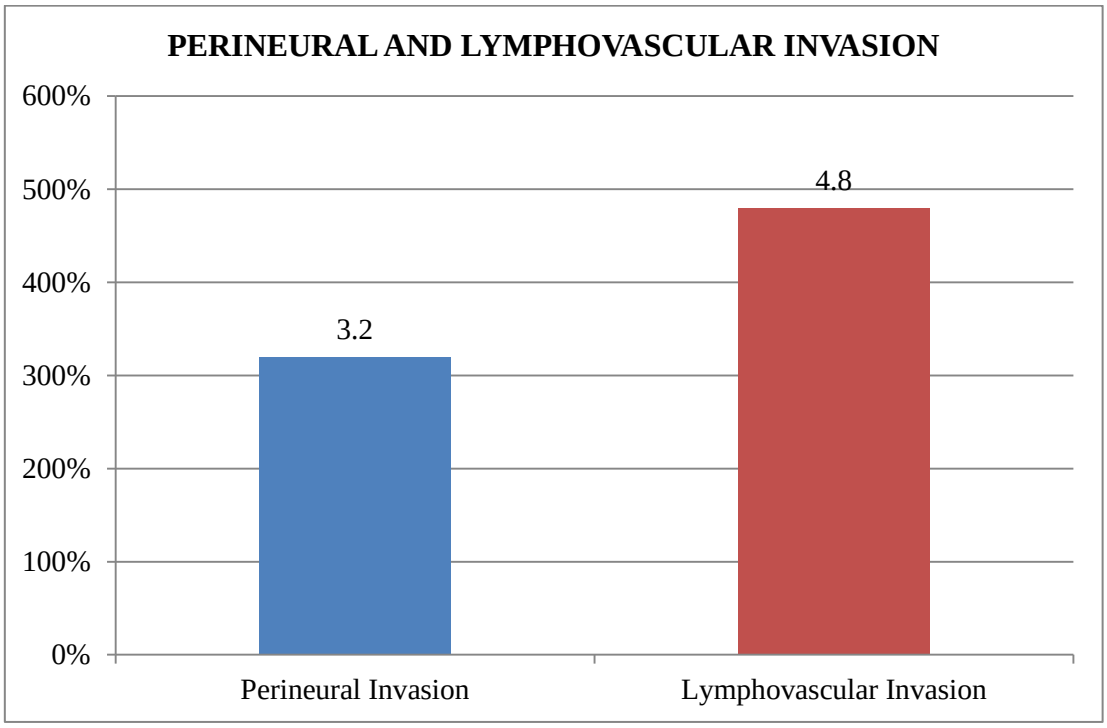

Chart 11 : Bar diagram showing Perineural Invasion and Lymphovascular Invasion in the study subjects

Table 14: Lymph node ratio (LNR) distribution among subjects

		Frequency	Percent(%)
LNR	<0.111	40	64.5
	0.111 to 0.200	3	4.8
	0.200 to 0.429	5	8.1
	>0.429	14	22.6
	Total	62	100.0

In the study, 64.5% of cases had LNR <0.111, 4.8% had LNR 0.111 to 0.200, 8.1% had LNR 0.200 to 0.429 and 22.6% of cases had LNR >0.429.

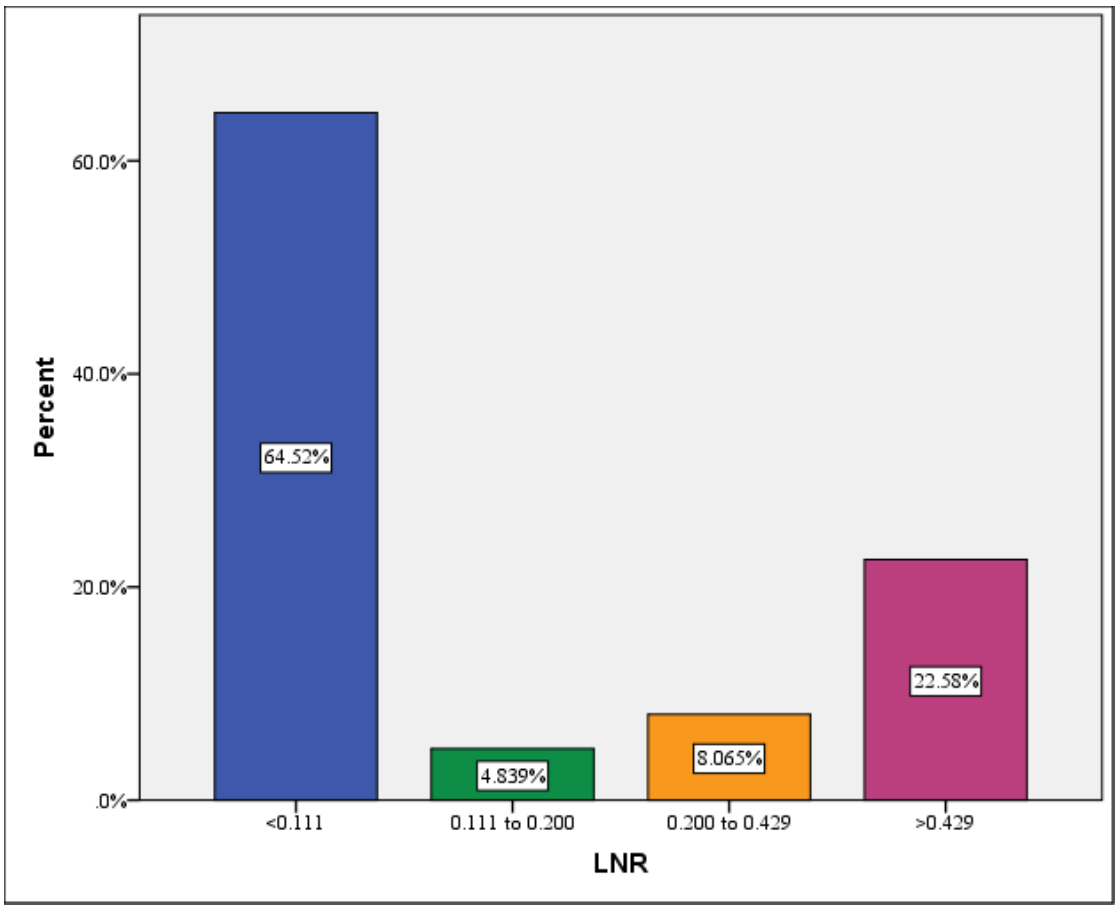

Chart 12 : Bar diagram showing LNR distribution among subjects

Table 15: CD 68 distribution among subjects

		Count	Percent (%)
CD 68	<10% of Cells	24	38.7%
	>10% to <50% of Cells Positive	24	38.7%
	>50% of Cells Positive	14	22.6%

In the study, 38.7% of cases expressed CD 68 in <10% of cells, 38.7% of cases expressed CD 68 in >10% to <50% of Cells and 22.6% of cases expressed CD 68 in >50% of Cells.

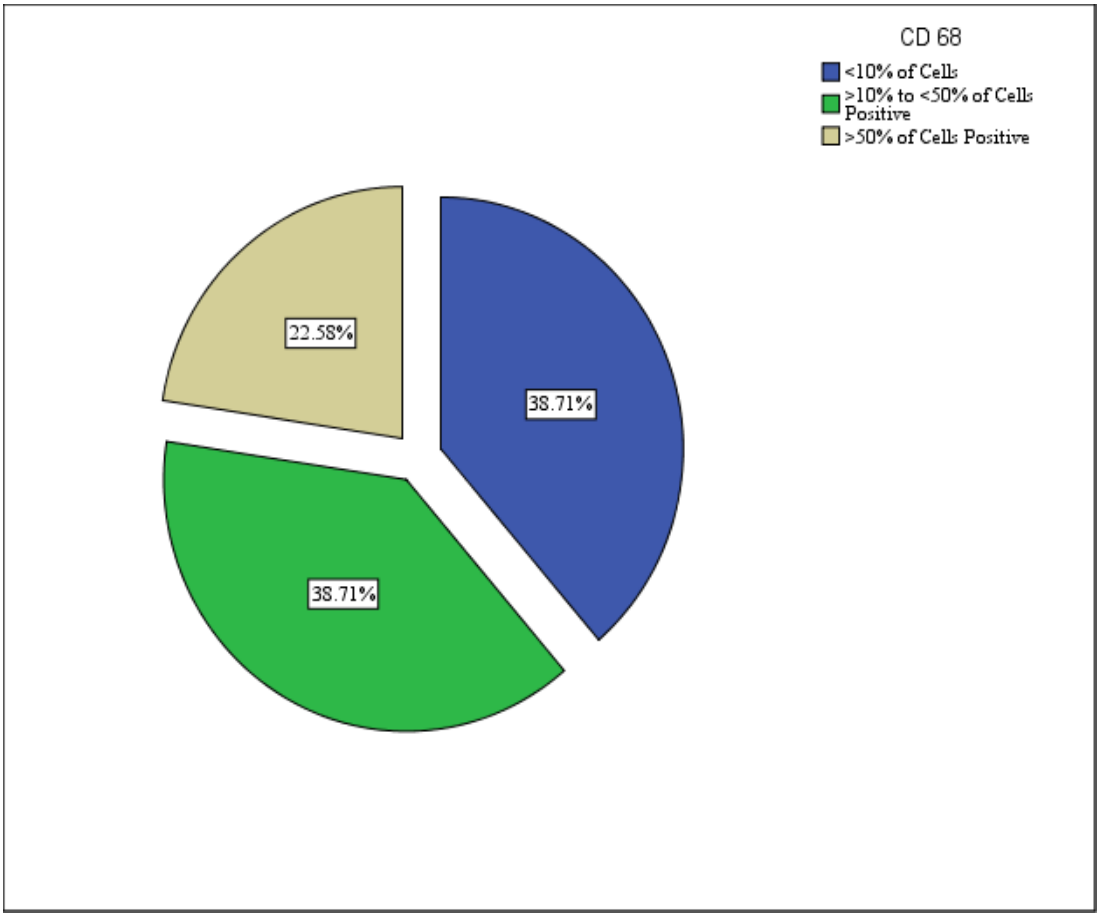

Chart 13 : Pie diagram showing distribution of CD 68 expression among subjects

Table 16 : CD 163 distribution among subjects

		Count	Percent (%)
CD 163	<10% of Cells	6	9.7%
	>10% to <50% of Cells Positive	36	58.1%
	>50% of Cells Positive	20	32.3%

In the study, 9.7% of cases expressed CD 163 in <10% of Cells, 58.1% of cases expressed CD 163 in >10% to <50% of Cells and 32.3% of cases expressed CD 163 in >50% of Cells.

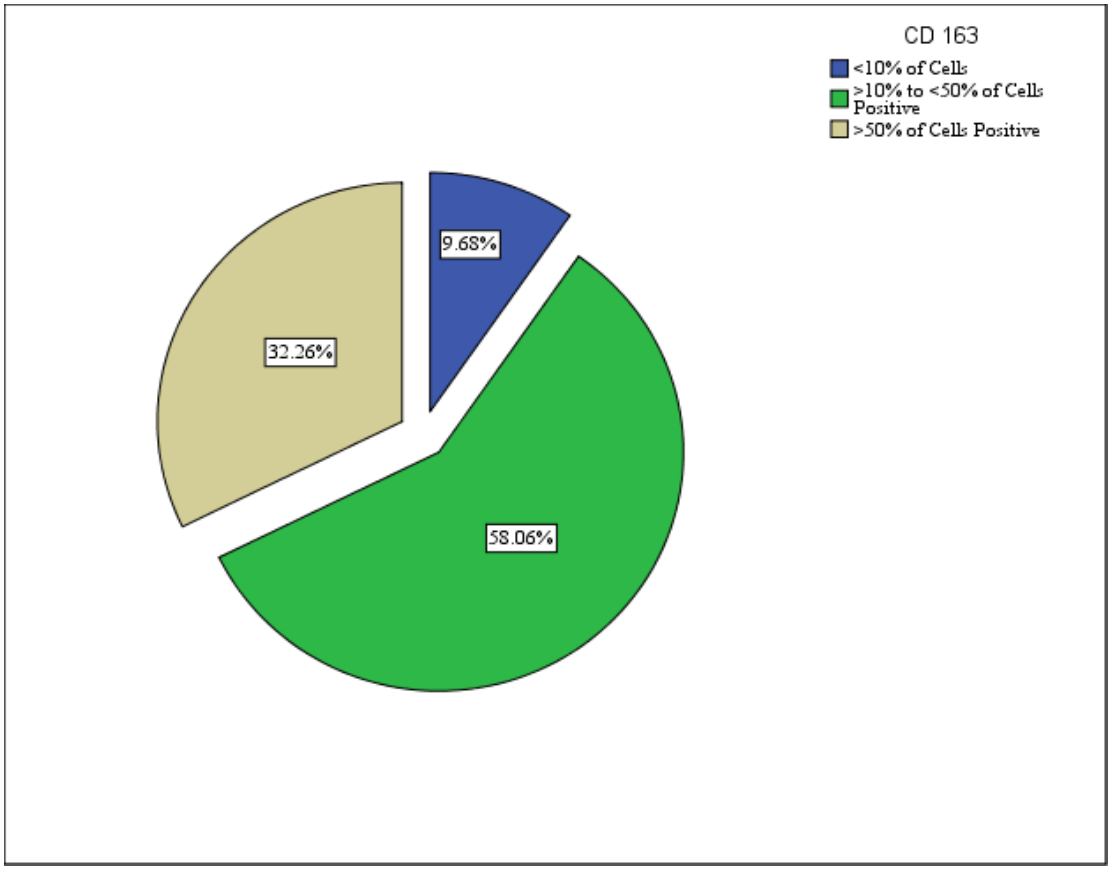

Chart 14: Pie diagram showing distribution of CD 163 expression among subjects

COMPARISION OF DIFFERENT PROGNOSTIC MARKERS WITH CD 68

DISCUSSION

DISCUSSION

Table 45 - Comparison of age distribution with other studies

Age	Gulubova M et al [40] (2013)	Forssell et al [41] (2007)	Present Study (2018)
≤ 60 years	66(32.5%)	90 (19.3%)	42 (67.7%)
> 60 years	137(67.5%)	137(67.5%)	20 (32.3%)

In the present study, the majority of the cases, n=42(67.7%) were less than 60 years of age and 20 (32.3%) cases were over the age of 60 years. Other studies done by Gulubova M et al [40] and Forssell et al [41] observed that majority of the cases, I.e 137(67.5%) and 137(67.5%) were above the age of 60 years respectively.

In the study, there was no significant association between age distribution and CD 68 and CD 163 expression. I.e the expression of CD 68 and CD 163 antigens are independent of the age of the patient in colo-rectal cancers.

Table 46 - Comparison of sex distribution with other studies

	Gulubova M et al [40] (2013)	Majek O et al [42] (2013)	Present study (2018)
Males	128 (61.0%)	86704 (52.5%)	39(62.9%)
Females	82 (39.0%)	78292 (47.5%)	23(37.1%)

The present study showed that maximum number of cases of colo-rectal cancers were in male population. This was similar to the observations made by Gulubova M et al [40] and Majek O et al [42] showing that incidence of colo-rectal cancers are more common in men than in women.

Though macrophage infiltration into the tumor stroma is considered as a prognostic factor, its prognostic association with the gender of the patient is not proved. In the present study involving 36 male cases and 23 female cases, there was no statistically significant correlation between the gender of the patient and expression of CD 68 and CD 163 showing that macrophages infiltrating the tumor stroma is independent of patient's gender.

Table 47 - Comparison of distribution of site of tumor with other studies

Site	Wei Q at al [44] (2016)	Pirzada MT et al [45] (2017)	Patra T et al [46] (2017)	Present study (2018)
Right colon	25(41.0%)	46 (9.6%)	87(23.2%)	16(25.8%)
Left colon	13(21.3%)	14(30.2%)	94(25%)	19(30.6%)
Rectum	23(37.7%)	287 (60.2%)	194(51.7%)	27(43.5%)

In the study, the tumors were broadly classified into right colon that includes ileocecal junction, cecum, ascending colon, hepatic flexure of transverse colon. The left-sided colon consisted of splenic flexure, descending colon and sigmoid colon and rectum. It was further subdivided into ascending colon, transverse colon, descending colon, sigmoid colon and rectum for further statistical analysis.

The maximum number of cases were rectal carcinomas which was similar to the study done by Pirzada MT et al [45] and Patra T et al [46] whereas maximum colo-rectal tumors were seen in right colon as per the observations made by Wei Q at al [44]

There was a statistically significant correlation between the site of tumor and CD 68 expression ($p = 0.037$) but not for CD 163.

It has been an established data that left sided colon cancers are associated with better prognosis than right sided colonic cancers[71]. In the present study, maximum number of tumors were located in left colon and significant correlation between the CD 68 antigen supports the concept that infiltration by M1 macrophages is a good a good prognostic factor.

In the present study, 39 (62.9%) cases were hemicolectomy specimens, 14(22.5%) cases underwent abdominal perineal resections and 9(14.5%) cases underwent anterior resection.

In the study, 8(12.9%) cases had proliferative growth pattern on gross, ulceroproliferative in 34(54.8%) cases and ulcerative or infiltrative growth pattern in 20(32.2%) cases.

There was no statistically significant correlation between the different growth patterns of tumor with CD 68 and CD 163 expression. This could be attributed to the concept that, though infiltrative growth patterns are considered to be associated with bad prognosis due to higher T stage, the infiltration of the macrophages into the tumor stroma does not depend on the type of tumor growth.

Table 48 - Comparision of size of tumor with other studies

Tumor size	Chen HC et al [47] (2017)	Present study (2018)
≤ 5 cms	143(64.7%)	39(62.9%)
>5 cms	78(35.3%)	23(37.09%)

In the study, majority of the cases were less than 5 cms I.e 39(62.9%) which is similar to the observations made by Chen HC et al [47]

There was a statistically significant correlation between the tumor size and CD 68 expression ($p = 0.044$) but no significance was seen with expression of CD 163.

Tumor size is a well proven prognostic factor in Colo-rectal cancers as smaller tumours are associated with better prognosis. In the study, as there was a significant correlation between CD 68 and size of the tumor, it supports the hypothesis that CD 68 positive M1 macrophages in the tumor stroma are a good prognostic markers and is associated with lesser T stage and better survival.

Table 49 - Comparison of Tumor grade with other studies

Tumor grade	Telfah A et al [48] (2015)	Resch A [49] (2015)	Present study (2018)
Well differentiated	37(7.4%)	27(18.6%)	20(32.2%)
Moderately differentiated	280(56%)	72(49.7%)	30(48.4%)
Poorly differentiated	138(36.6%)	46(31.7%)	12(19.3%)

Telfah A et al [48] and Resch A [49] studied the grading of colo-rectal carcinomas and noted that moderately differentiated adenocarcinomas were the most common grade followed by poorly differentiated type. Similar observations were made in the present study that moderately differentiated carcinomas were the most common grade encountered and accounted to 48.4% of cases.

There was a statistically significant association between Grade of the tumor and CD 68 expression but not with CD163.

The moderately differentiated adenocarcinomas and well differentiated adenocarcinomas which are the majority in the present study group are associated with better prognosis compared to poorly differentiated adenocarcinomas and M1 macrophages posses antigen presenting molecules, which is co-stimulatory receptor for lymphocytes and many pro inflammatory cytokines on their surface. This immune mechanism is considered as body's response against the tumor cells and helps in tumor differentiation and further supports the hypothesis that CD 68 expression is a good prognostic marker in colo-rectal cancers.

Table 50 - Comparision of TNM staging with other studies

TNM staging	Vlad C et al [50] (2015)	Zhao M et al [51] (2017)	Present study (2018)
I	56(17.6%)	78,070(26.5%)	4(6.4%)
II	75(23.6%)	79,906(27.2%)	16(25.8%)
III	178(56.3%)	80,865(27.5%)	32(51.6%)
IV	8(2.5%)	54,775(18.6%)	10(16.1%)

In the present study, maximum number of cases were in stage III category (51.6%) which is similar to the observations done by Vlad C et al [50] and Zhao M et al [51] in their studies. Stage III was followed by stage II(25.8%), Stage IV(16.1%) and stage I(6.4%).

The stage of the tumor was statistically significant only with CD 163 expression and not with CD 68.

In the present study, stage III and stage IV tumors constituted the majority and are designated as advance disease which is associated with poorer outcomes. The significant association of CD 163 with the stage in the study adds on to the theory put forth by Eden S et al[13,14] that CD 163 which is a marker for M2 macrophages is pro-tumorogenic and associated with bad prognosis.

Table 51 - Comparison of T staging with other studies

T stage	Kim SM et al [52] (2017)	Ladeira KM et al [53] (2016)	Present study (2018)
T1	1(0.97%)	63 (5.9%)	4(6.4%)
T2	3(2.91%)	148 (13.9%)	16(25.8%)
T3	50(48.5%)	758 (71.2%)	32(51.6%)
T4	49(47.5%)	63 (5.9%)	10(16.1%)

In concordance with the observations made in the studies conducted by Kim SM et al [52] and Ladeira KM [53],

The maximum number of cases were in the T3 stage which means the maximum number of cases invaded through muscularis propria into subserosa or into non-peritonealized pericolic or perirectal tissues which is associated with higher stage. It is similar to the observations made in the present study with 51.6% (n=32) of cases in T3 stage.

There was a statistically significant association between expression of CD 163 with the T stage whereas CD 68 was not showing any significant correlation.

The expression of CD 163 by M2 macrophages is considered to be a bad prognostic factor as they are hypothesized to promote tumor growth by releasing growth factors and promoting angiogenesis [12]. The significant association between Cd 163 expression and higher T stage supports this hypothesis.

Table 52 - Comparison of N staging with other studies

N stage	Liu Q et al [54] (2018)	Soylu L et al [55] (2017)	Moug SJ et al [56] (2009)	Present study (2018)
N0	28,935(66.98%)	112(58.9%)	120(61.5%)	39(62.9%)
N1	9936(23. %)	45(23.7%)	49(25.1%)	21(33.8%)
N2	4325(10.01%)	33(17.4%)	26(13.3%)	2(3.22%)

According to the observations made by Liu Q et al [54] , Soylu L et al [55] and Moug SJ et al [56], maximum number of cases were in N0 category with 66.98% , 58.9% and 61.5% respectively and the least number of cases were seen on N2 category with 10.01%, 17.4% and 13.3% respectively. Similar trend was seen in the present study with maximum number of cases in N0 category (62.9%) and least number of cases in N2 category (3.22%).

There was a statistically significant correlation between N stage and CD 163 expression whereas CD 68 did not show any correlation.

Shabo I et al [12] studied the expression of CD 163 in colo-rectal cancers and concluded that its expression is a bad prognostic factor, but the N stage was not included in his study. In the present study, majority of cases were in N0 stage and the observation in the N stage showed that CD 163 is a good prognostic factor which is in contrast to the study done by Shabo I et al [12]. This could be due to the more number of cases in N0 category and a larger sample size could provide a better understanding in this regard.

Table 53 - Comparison of Perineural invasion with other studies

Perineural invasion	Huh JW et al [57] (2010)	Liebig C et al [58] (2009)	Sukhni ES et al [59] (2017)	Present study (2018)
Present	57 (16.7%)	55 (22.1%)	15,734 (11.1%)	2 (3.33%)
Absent	284 (83.28%)	194 (77.9%)	1,26,300(88.9%)	60 (96.7%)

Perineural invasion is one of the important prognostic factor in colo-rectal cancers. In the present study, only two cases had perineural invasion accounting to 3.33%. Higher number of cases with perineural invasion was seen in study by Liebig C et al [58] with 22.1% followed by Huh JW et al [57] and Sukhni ES et al [59] with 16.7% and 11.1% respectively.

Perineural invasion is one of the proved bad prognostic factor in Colo-rectal cancer. However, in the present study, there was no statistically significant association between CD 68 and CD 163 expression with perineural invasion. This suggests that perineural invasion is an independent prognostic variable irrespective of CD 68 and CD 163 expression.

Table 54 - Comparision of Lymphovascular invasion with other studies

Lympho vascular invasion	Lim SB et al [60] (2010)	Chang CS et al [61] (2012)	Lopes CR et al [62] (2012)	Present study (2018)
Present	610 (25.2%)	16 (5.5%)	112(44.6%)	3(4.8%)
Absent	1807(74.76%)	276 (90.9%)	139(55.37%)	59(95.2%)

Among the observations made in different studies, a study by Lopes CR et al [62] showed higher number of cases (44.6%) showing lymphovascular invasion followed by 25.2% of cases as observed by Lim SB et al [60].

The present study had only 4.8% of cases with lymphovascular invasion which is similar to the observations made by Chang CS et al [61](5.5%).

There was no statistically significant correlation between expression of CD 68 and CD 163 with lymphovascular invasion.

The loss of significance of CD 68 and CD 163 with lymphovascular invasion may be due to less number of cases with lymphovascular invasion cases(4.8%) encountered in the study. Further studies with more number of lymphovascular invasion positive cases can provide better reliable data in this regard.

Table 55 - Comparision of Lymph node ratio (LNR) with other studies

	LNR	Ren QJ et al [70] (2012)	Present study (2018)
LNR 1	<0.111	36 (24.8%)	40 (64.5%)
LNR 2	0.111 to 0.200	37 (25.5%)	3 (4.8%)
LNR 3	0.200 to 0.429	37 (25.5%)	5 (8%)
LNR 4	>0.429	35 (24.1%)	14(22.5%)

Lymph node ratio is one of the important, newer factors in determining the prognosis of Colo rectal cancers. It has also been studied in tumors of stomach, pancreas, bladder and breast [65]. Lymph node ratio is the proportion of the number of Lymph node with tumor deposits to the number of Lymph nodes examined[63]. It has also been studied that increased harvesting of Lymph nodes during surgery in colorectal cancers is associated with better outcomes [64]. Different cut-off values have been studied by various authors for determining Lymph node ratio. In general, higher Lymph node ratio is associated with poor 3 year relapse free survival, higher tumor stage, perineural invasion and overall survival [66,67].

Ren QJ et al [70] studies LNR in colo rectal cancer patients with Stage III disease and observed that maximum number cases were in LNR 2 and LNR 3 which is associated with poor prognosis. In the present study, maximum number of cases were in LNR1 category. This may be attributed to the concept that Ren QJ et al [70] used only stage III tumors that had higher chance of Lymph node metatstasis.

There was a statistically significant relationship between Lymph node ratio and CD 163 expression but not with expression of CD 68.

LNR has been proved as a bad prognostic marker in breast cancer. Numerous studies are being done in colo-rectal cancers to assess its prognostic significance. M2 macrophages are hypothesized to be tumor promotive and are associated with bad prognosis. The significant correlation in the present study adds on to CD163 as a bad prognostic marker.

Table 56 - Correlation of Expression of CD 68 and CD 163

			CD 68			Total
			<10% of Cells	>10% to <50% of Cells Positive	>50% of Cells Positive	
CD 163	<10% of Cells	Count	1	3	2	6
	>10% to <50% of Cells Positive	Count	16	10	10	36
	>50% of Cells Positive	Count	7	11	2	20
Total		Count	24	24	14	62

There was no statistically significant correlation between expression of CD 163 with CD 68 expression.

CD 68 stains M1 macrophages that are considered to be anti-tumorigenic whereas CD 163 stains M2 macrophages that are pro-tumorigenic and both these macrophages have contrary effects on tumor progression. This is supported by no statistical significance between these two entities in the present study.

Conclusion

CONCLUSION

Majority of the patients were in the golden age group of less than 60 years.

CD 68 expression was associated with better prognostic factors such as smaller size of tumor, lesser grade and lesser Lymph node ratio(LNR).

CD 163 expression was associated with poorer prognostic factors such as higher T stage, Higher N stage, and higher values of Lymph node ratio(LNR).

Hence, CD 68 and CD 163 can be used as novel biomarkers in assessing the prognosis in Colo-rectal cancer patients. Further studies may help in improving the therapeutic modalities by targeted therapies.

SUMMARY

1. The present study was conducted in the Department of Pathology , Sri Devaraj Urs Medical College, Tamaka, Kolar from December 2016 to September 2018. Also,Retrospective cases from January 2008 to November 2016 were included in the study.
2. A total of 62 cases were studied of which 39 were males and 23 were females
3. Majority of the subjects were less than 60 years of age 42 cases(67.7%)
4. The most common site of tumor was Rectum 27 cases,(43.5%) followed by ascending colon 13 cases (21%).
5. The most common growth was Ulceroproliferative type, 34 cases(54.8%)
6. Majority of the tumors were less than 5 cms, 39 cases(62.9%)
7. The most common grade was moderately differentiated adenocarcinoma, 30 cases (48.4%)
8. The most common T stage was T3, 32 cases(51.6%) and most common N stage was N0, 39 cases, (62.9%)
9. Maximum number of cases were in Stage III, 23 cases(37.1%)
10. Perineural invasion was seen in only 2 cases (3.2%) and lymphovascular invasion was seen in 3 cases(4.8%)
11. Maximum number of cases (64.5%) were in Lymph node ratio less than <0.111.
12. CD 68 expression was associated with smaller size of tumor, lesser grade and lesser Lymph node ratio(LNR).
13. CD 163 expression was associated with higher T stage, Higher N stage, and higher values of Lymph node ratio(LNR).
